# Contents

<b>Chapter 2: Probability</b>	<b>1</b>
2.2 Samples Spaces and the Algebra of Sets	1
2.3 The Probability Function	6
2.4 Conditional Probability	7
2.5 Independence	13
2.6 Combinatorics	17
2.7 Combinatorial Probability	24
<b>Chapter 3: Random Variables</b>	<b>27</b>
3.2 Binomial and Hypergeometric Probabilities	27
3.3 Discrete Random Variables	36
3.4 Continuous Random Variables	41
3.5 Expected Values	44
3.6 The Variance	52
3.7 Joint Densities	57
3.8 Transforming and Combining Random Variables	69
3.9 Further Properties of the Mean and Variance	73
3.10 Order Statistics	79
3.11 Conditional Densities	82
3.12 Moment-Generating Functions	88
<b>Chapter 4: Special Distributions</b>	<b>93</b>
4.2 The Poisson Distribution	93
4.3 The Normal Distribution	98
4.4 The Geometric Distribution	105
4.5 The Negative Binomial Distribution	107
4.6 The Gamma Distribution	109
<b>Chapter 5: Estimation</b>	<b>111</b>
5.2 Estimating Parameters: The Method of Maximum Likelihood and Method of Moments	111
5.3 Interval Estimation	118
5.4 Properties of Estimators	123
5.5 Minimum-Variance Estimators: The Cramér-Rao Lower Bound	128
5.6 Sufficient Estimators	130
5.7 Consistency	133
5.8 Bayesian Estimation	135

<b>Chapter 6: Hypothesis Testing</b>	137
6.2 The Decision Rule	137
6.3 Testing Binomial Data	138
6.4 Type I and Type II Errors	139
6.5 A Notion of Optimality: The Generalized Likelihood Ratio	144
<b>Chapter 7: Inferences Based on the Normal Distribution</b>	147
7.3 Deriving the Distribution of $\frac{\bar{Y}-\mu}{S/\sqrt{n}}$	147
7.4 Drawing Inferences About $\mu$	150
7.5 Drawing Inferences About $\sigma^2$	156
<b>Chapter 8: Types of Data: A Brief Overview</b>	161
8.2 Classifying Data	161
<b>Chapter 9: Two-Sample Inference</b>	163
9.2 Testing $H_0 : \mu_X = \mu_Y$	163
9.3 Testing $H_0 : \sigma_X^2 = \sigma_Y^2$ —The $F$ Test	166
9.4 Binomial Data: Testing $H_0 : p_X = p_Y$	168
9.5 Confidence Intervals for the Two-Sample Problem	170
<b>Chapter 10: Goodness-of-Fit Tests</b>	173
10.2 The Multinomial Distribution	173
10.3 Goodness-of-Fit Tests: All Parameters Known	175
10.4 Goodness-of-Fit Tests: Parameters Unknown	178
10.5 Contingency Tables	185
<b>Chapter 11: Regression</b>	189
11.2 The Method of Least Squares	189
11.3 The Linear Model	199
11.4 Covariance and Correlation	204
11.5 The Bivariate Normal Distribution	208
<b>Chapter 12: The Analysis of Variance</b>	211
12.2 The $F$ test	211
12.3 Multiple Comparisons: Tukey's Method	214

12.4	Testing Subhypotheses with Constrasts .....	216
12.5	Data Transformations .....	218
Appendix 12.A.2	The Distribution of $\frac{SSTR/(k-1)}{SSE/(n-k)}$ When $H_1$ Is True .....	218
<b>Chapter 13: Randomized Block Designs .....</b>		<b>221</b>
13.2	The $F$ Test for a Randomized Block Design .....	221
13.3	The Paired $t$ Test.....	224
<b>Chapter 14: Nonparametric Statistics.....</b>		<b>229</b>
14.2	The Sign Test .....	229
14.3	Wilcoxon Tests.....	232
14.4	The Kruskal-Wallis Test .....	236
14.5	The Friedman Test.....	239
14.6	Testing for Randomness.....	241

# Chapter 2: Probability

## Section 2.2: Sample Spaces and the Algebra of Sets

- 2.2.1**  $S = \{(s, s, s), (s, s, f), (s, f, s), (f, s, s), (s, f, f), (f, s, f), (f, f, s), (f, f, f)\}$   
 $A = \{(s, f, s), (f, s, s)\}; B = \{(f, f, f)\}$
- 2.2.2** Let  $(x, y, z)$  denote a red  $x$ , a blue  $y$ , and a green  $z$ .  
Then  $A = \{(2, 2, 1), (2, 1, 2), (1, 2, 2), (1, 1, 3), (1, 3, 1), (3, 1, 1)\}$
- 2.2.3**  $(1, 3, 4), (1, 3, 5), (1, 3, 6), (2, 3, 4), (2, 3, 5), (2, 3, 6)$
- 2.2.4** There are 16 ways to get an ace and a 7, 16 ways to get a 2 and a 6, 16 ways to get a 3 and a 5, and 6 ways to get two 4's, giving 54 total.
- 2.2.5** The outcome sought is  $(4, 4)$ . It is "harder" to obtain than the set  $\{(5, 3), (3, 5), (6, 2), (2, 6)\}$  of other outcomes making a total of 8.
- 2.2.6** The set  $N$  of five card hands in hearts that are not flushes are called *straight flushes*. These are five cards whose denominations are consecutive. Each one is characterized by the lowest value in the hand. The choices for the lowest value are A, 2, 3, ..., 10. (Notice that an ace can be high or low). Thus,  $N$  has 10 elements.
- 2.2.7**  $P = \{\text{right triangles with sides } (5, a, b): a^2 + b^2 = 25\}$
- 2.2.8**  $A = \{SSBBBB, SBSBBB, SBBSBB, SBBBSB, BSSBBB, BSBSBB, BSBBBS, BBSSBB, BBSBSB, BBBSSB\}$
- 2.2.9** (a)  $S = \{(0, 0, 0, 0), (0, 0, 0, 1), (0, 0, 1, 0), (0, 0, 1, 1), (0, 1, 0, 0), (0, 1, 0, 1), (0, 1, 1, 0), (0, 1, 1, 1), (1, 0, 0, 0), (1, 0, 0, 1), (1, 0, 1, 0), (1, 0, 1, 1), (1, 1, 0, 0), (1, 1, 0, 1), (1, 1, 1, 0), (1, 1, 1, 1)\}$   
(b)  $A = \{(0, 0, 1, 1), (0, 1, 0, 1), (0, 1, 1, 0), (1, 0, 0, 1), (1, 0, 1, 0), (1, 1, 0, 0)\}$   
(c)  $1 + k$
- 2.2.10** (a)  $S = \{(1, 1), (1, 2), (1, 4), (2, 1), (2, 2), (2, 4), (4, 1), (4, 2), (4, 4)\}$   
(b)  $\{2, 3, 4, 5, 6, 8\}$
- 2.2.11** Let  $p_1$  and  $p_2$  denote the two perpetrators and  $i_1, i_2$ , and  $i_3$ , the three in the lineup who are innocent.  
Then  $S = \{(p_1, i_1), (p_1, i_2), (p_1, i_3), (p_2, i_1), (p_2, i_2), (p_2, i_3), (p_1, p_2), (i_1, i_2), (i_1, i_3), (i_2, i_3)\}$ .  
The event  $A$  contains every outcome in  $S$  except  $(p_1, p_2)$ .
- 2.2.12** The quadratic equation will have complex roots—that is, the event  $A$  will occur—if  $b^2 - 4ac < 0$ .
- 2.2.13** In order for the shooter to win with a point of 9, one of the following (countably infinite) sequences of sums must be rolled:  $(9, 9)$ ,  $(9, \text{no } 7 \text{ or no } 9, 9)$ ,  $(9, \text{no } 7 \text{ or no } 9, \text{no } 7 \text{ or no } 9, 9)$ , ...

**2.2.14** Let  $(x, y)$  denote the strategy of putting  $x$  white chips and  $y$  red chips in the first urn (which results in  $10 - x$  white chips and  $10 - y$  red chips being in the second urn). Then  $S = \{(x, y) : x = 0, 1, \dots, 10, y = 0, 1, \dots, 10, \text{ and } 1 \leq x + y \leq 19\}$ . Intuitively, the optimal strategies are  $(1, 0)$  and  $(9, 10)$ .

**2.2.15** Let  $A_k$  be the set of chips put in the urn at  $1/2^k$  minute until midnight. For example,  $A_1 = \{11, 12, 13, 14, 15, 16, 17, 18, 19, 20\}$ . Then the set of chips in the urn at midnight is  $\bigcup_{k=1}^{\infty} (A_k - \{k+1\}) = \emptyset$ .

**2.2.16** move arrow on first figure raise B by 1

**2.2.17** If  $x^2 + 2x \leq 8$ , then  $(x + 4)(x - 2) \leq 0$  and  $A = \{x : -4 \leq x \leq 2\}$ . Similarly, if  $x^2 + x \leq 6$ , then  $(x + 3)(x - 2) \leq 0$  and  $B = \{x : -3 \leq x \leq 2\}$ . Therefore,  $A \cap B = \{x : -3 \leq x \leq 2\}$  and  $A \cup B = \{x : -4 \leq x \leq 2\}$ .

**2.2.18**  $A \cap B \cap C = \{x : x = 2, 3, 4\}$

**2.2.19** The system fails if either the first pair fails or the second pair fails (or both pairs fail). For either pair to fail, though, both of its components must fail. Therefore,  $A = (A_{11} \cap A_{21}) \cup (A_{12} \cap A_{22})$ .

**2.2.21** 40

**2.2.22** (a)  $\{E1, E2\}$  (b)  $\{S1, S2, T1, T2\}$  (c)  $\{A, I\}$

**2.2.23** (a) If  $s$  is a member of  $A \cup (B \cap C)$  then  $s$  belongs to  $A$  or to  $B \cap C$ . If it is a member of  $A$  or of  $B \cap C$ , then it belongs to  $A \cup B$  and to  $A \cup C$ . Thus, it is a member of  $(A \cup B) \cap (A \cup C)$ . Conversely, choose  $s$  in  $(A \cup B) \cap (A \cup C)$ . If it belongs to  $A$ , then it belongs to  $A \cup (B \cap C)$ . If it does not belong to  $A$ , then it must be a member of  $B \cap C$ . In that case it also is a member of  $A \cup (B \cap C)$ .

- (b) If  $s$  is a member of  $A \cap (B \cup C)$  then  $s$  belongs to  $A$  and to  $B \cup C$ . If it is a member of  $B$ , then it belongs to  $A \cap B$  and, hence,  $(A \cap B) \cup (A \cap C)$ . Similarly, if it belongs to  $C$ , it is a member of  $(A \cap B) \cup (A \cap C)$ . Conversely, choose  $s$  in  $(A \cap B) \cup (A \cap C)$ . Then it belongs to  $A$ . If it is a member of  $A \cap B$  then it belongs to  $A \cap (B \cup C)$ . Similarly, if it belongs to  $A \cap C$ , then it must be a member of  $A \cap (B \cup C)$ .

**2.2.24** Let  $B = A_1 \cup A_2 \cup \dots \cup A_k$ . Then  $A_1^C \cap A_2^C \cap \dots \cap A_k^C = (A_1 \cup A_2 \cup \dots \cup A_k)^C = B^C$ . Then the expression is simply  $B \cup B^C = S$ .

- 2.2.25** (a) Let  $s$  be a member of  $A \cup (B \cap C)$ . Then  $s$  belongs to either  $A$  or  $B \cap C$  (or both). If  $s$  belongs to  $A$ , it necessarily belongs to  $(A \cup B) \cap C$ . If  $s$  belongs to  $B \cap C$ , it belongs to  $B$  or  $C$  or both, so it must belong to  $(A \cup B) \cap C$ . Now, suppose  $s$  belongs to  $(A \cup B) \cap C$ . Then it belongs to either  $A \cup B$  or  $C$  or both. If it belongs to  $C$ , it must belong to  $A \cup (B \cap C)$ . If it belongs to  $A \cup B$ , it must belong to either  $A$  or  $B$  or both, so it must belong to  $A \cup (B \cap C)$ .
- (b) Suppose  $s$  belongs to  $A \cap (B \cap C)$ , so it is a member of  $A$  and also  $B \cap C$ . Then it is a member of  $A$  and of  $B$  and  $C$ . That makes it a member of  $(A \cap B) \cap C$ . Conversely, if  $s$  is a member of  $(A \cap B) \cap C$ , a similar argument shows it belongs to  $A \cap (B \cap C)$ .

- 2.2.26** (a)  $A^C \cap B^C \cap C^C$   
 (b)  $A \cap B \cap C$   
 (c)  $A \cap B^C \cap C^C$   
 (d)  $(A \cap B^C \cap C^C) \cup (A^C \cap B \cap C^C) \cup (A^C \cap B^C \cap C)$   
 (e)  $(A \cap B \cap C^C) \cup (A \cap B^C \cap C) \cup (A^C \cap B \cap C)$

**2.2.27**  $A$  is a subset of  $B$ .

- 2.2.28** (a)  $\{0\} \cup \{x: 5 \leq x \leq 10\}$   
 (b)  $\{x: 3 \leq x < 5\}$   
 (c)  $\{x: 0 < x \leq 7\}$   
 (d)  $\{x: 0 < x < 3\}$   
 (e)  $\{x: 3 \leq x \leq 10\}$   
 (f)  $\{x: 7 < x \leq 10\}$

- 2.2.29** (a)  $B$  and  $C$   
 (b)  $B$  is a subset of  $A$ .

- 2.2.30** (a)  $A_1 \cap A_2 \cap A_3$   
 (b)  $A_1 \cup A_2 \cup A_3$

The second protocol would be better if speed of approval matters. For very important issues, the first protocol is superior.

- 2.2.31** Let  $A$  and  $B$  denote the students who saw the movie the first time and the second time, respectively. Then  $N(A) = 850$ ,  $N(B) = 690$ , and  $N[(A \cup B)^C] = 4700$  (implying that  $N(A \cup B) = 1300$ ). Therefore,  $N(A \cap B) =$  number who saw movie twice  $= 850 + 690 - 1300 = 240$ .

2.2.32

(a)

$$(A \cap B)^C = A^C \cup B^C$$

(b)

$$(A \cup B)^C = A^C \cap B^C$$

2.2.33

(a)

$$A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$$

(b)

$$A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$$

2.2.34

(a)

$$A \cup (B \cup C)$$

$$(A \cup B) \cup C$$

(b)

$$A \cap (B \cap C)$$

$$(A \cap B) \cap C$$

2.2.35

$A$  and  $B$  are subsets of  $A \cup B$ .

2.2.36

2.2.37

Let  $A$  be the set of those with MCAT scores  $\geq 27$  and  $B$  be the set of those with GPAs  $\geq 3.5$ . We are given that  $N(A) = 1000$ ,  $N(B) = 400$ , and  $N(A \cap B) = 300$ . Then  $N(A^c \cap B^c) = N[(A \cup B)^c] = 1200 - N(A \cup B) = 1200 - [(N(A) + N(B) - N(A \cap B))]$   
 $= 1200 - [(1000 + 400 - 300)] = 100$ . The requested proportion is  $100/1200$ .

2.2.38

$$N(A \cup B \cup C) = N(A) + N(B) + N(C) - N(A \cap B) - N(A \cap C) - N(B \cap C) + N(A \cap B \cap C)$$

2.2.39

Let  $A$  be the set of those saying “yes” to the first question and  $B$  be the set of those saying “yes” to the second question. We are given that  $N(A) = 600$ ,  $N(B) = 400$ , and  $N(A^c \cap B) = 300$ . Then  $N(A \cap B) = N(B) - N(A^c \cap B) = 400 - 300 = 100$ .  $N(A \cap B^c) = N(A) - N(A \cap B) = 600 - 100 = 500$ .

2.2.40

$$N[(A \cap B)^c] = 120 - N(A \cup B) = 120 - [N(A^c \cap B) + N(A \cap B^c) + N(A \cap B)]$$

$$= 120 - [50 + 15 + 2] = 53$$

## Section 2.3: The Probability Function

**2.3.1** Let  $L$  and  $V$  denote the sets of programs with offensive language and too much violence, respectively. Then  $P(L) = 0.42$ ,  $P(V) = 0.27$ , and  $P(L \cap V) = 0.10$ .  
Therefore,  $P(\text{program complies}) = P((L \cup V)^c) = 1 - [P(L) + P(V) - P(L \cap V)] = 0.41$ .

**2.3.2**  $P(A \text{ or } B \text{ but not both}) = P(A \cup B) - P(A \cap B) = P(A) + P(B) - P(A \cap B) - P(A \cap B)$   
 $= 0.4 + 0.5 - 0.1 - 0.1 = 0.7$

**2.3.3** (a)  $1 - P(A \cap B)$   
(b)  $P(B) - P(A \cap B)$

**2.3.4**  $P(A \cup B) = P(A) + P(B) - P(A \cap B) = 0.3$ ;  $P(A) - P(A \cap B) = 0.1$ . Therefore,  $P(B) = 0.2$ .

**2.3.5** No.  $P(A_1 \cup A_2 \cup A_3) = P(\text{at least one "6" appears}) = 1 - P(\text{no 6's appear}) = 1 - \left(\frac{5}{6}\right)^3 \neq \frac{1}{2}$ .  
The  $A_i$ 's are not mutually exclusive, so  $P(A_1 \cup A_2 \cup A_3) \neq P(A_1) + P(A_2) + P(A_3)$ .

**2.3.6**

$$P(A \text{ or } B \text{ but not both}) = 0.5 - 0.2 = 0.3$$

**2.3.7**

By inspection,  $B = (B \cap A_1) \cup (B \cap A_2) \cup \dots \cup (B \cap A_n)$ .

**2.3.8**

- 2.3.9**  $P(\text{odd man out}) = 1 - P(\text{no odd man out}) = 1 - P(HHH \text{ or } TTT) = 1 - \frac{2}{8} = \frac{3}{4}$
- 2.3.10**  $A = \{2, 4, 6, \dots, 24\}$ ;  $B = \{3, 6, 9, \dots, 24\}$ ;  $A \cap B = \{6, 12, 18, 24\}$ .  
Therefore,  $P(A \cup B) = P(A) + P(B) - P(A \cap B) = \frac{12}{24} + \frac{8}{24} - \frac{4}{24} = \frac{16}{24}$ .
- 2.3.11** Let  $A$ : State wins Saturday and  $B$ : State wins next Saturday. Then  $P(A) = 0.10$ ,  $P(B) = 0.30$ , and  $P(\text{lose both}) = 0.65 = 1 - P(A \cup B)$ , which implies that  $P(A \cup B) = 0.35$ . Therefore,  $P(A \cap B) = 0.10 + 0.30 - 0.35 = 0.05$ , so  $P(\text{State wins exactly once}) = P(A \cup B) - P(A \cap B) = 0.35 - 0.05 = 0.30$ .
- 2.3.12** Since  $A_1$  and  $A_2$  are mutually exclusive and cover the entire sample space,  $p_1 + p_2 = 1$ .  
But  $3p_1 - p_2 = \frac{1}{2}$ , so  $p_2 = \frac{5}{8}$ .
- 2.3.13** Let  $F$ : female is hired and  $T$ : minority is hired. Then  $P(F) = 0.60$ ,  $P(T) = 0.30$ , and  $P(F^C \cap T^C) = 0.25 = 1 - P(F \cup T)$ . Since  $P(F \cup T) = 0.75$ ,  $P(F \cap T) = 0.60 + 0.30 - 0.75 = 0.15$ .
- 2.3.14** The smallest value of  $P[(A \cup B \cup C)^C]$  occurs when  $P(A \cup B \cup C)$  is as large as possible. This, in turn, occurs when  $A$ ,  $B$ , and  $C$  are mutually disjoint. The largest value for  $P(A \cup B \cup C)$  is  $P(A) + P(B) + P(C) = 0.2 + 0.1 + 0.3 = 0.6$ . Thus, the smallest value for  $P[(A \cup B \cup C)^C]$  is 0.4.
- 2.3.15** (a)  $X^C \cap Y = \{(H, T, T, H), (T, H, H, T)\}$ , so  $P(X^C \cap Y) = 2/16$   
(b)  $X \cap Y^C = \{(H, T, T, T), (T, T, T, H), (T, H, H, H), (H, H, H, T)\}$  so  $P(X \cap Y^C) = 4/16$
- 2.3.16**  $A = \{(1, 5), (2, 4), (3, 3), (4, 2), (5, 1)\}$   
 $A \cap B^C = \{(1, 5), (3, 3), (5, 1)\}$ , so  $P(A \cap B^C) = 3/36 = 1/12$ .
- 2.3.17**  $A \cap B, (A \cap B) \cup (A \cap C), A, A \cup B, S$
- 2.3.18** Let  $A$  be the event of getting arrested for the first scam;  $B$ , for the second. We are given  $P(A) = 1/10$ ,  $P(B) = 1/30$ , and  $P(A \cap B) = 0.0025$ . Her chances of not getting arrested are  $P[(A \cup B)^C] = 1 - P(A \cup B) = 1 - [P(A) + P(B) - P(A \cap B)] = 1 - [1/10 + 1/30 - 0.0025] = 0.869$

## Section 2.4: Conditional Probability

- 2.4.1**  $P(\text{sum} = 10 | \text{sum exceeds } 8) = \frac{P(\text{sum} = 10 \text{ and sum exceeds } 8)}{P(\text{sum exceeds } 8)}$   

$$= \frac{P(\text{sum} = 10)}{P(\text{sum} = 9, 10, 11, \text{ or } 12)} = \frac{3/36}{4/36 + 3/36 + 2/36 + 1/36} = \frac{3}{10}.$$

**2.4.2**  $P(A|B) + P(B|A) = 0.75 = \frac{P(A \cap B)}{P(B)} + \frac{P(A \cap B)}{P(A)} = \frac{10P(A \cap B)}{4} + 5P(A \cap B)$ , which implies that  $P(A \cap B) = 0.1$ .

**2.4.3** If  $P(A|B) = \frac{P(A \cap B)}{P(B)} < P(A)$ , then  $P(A \cap B) < P(A) \cdot P(B)$ .

It follows that  $P(B|A) = \frac{P(A \cap B)}{P(A)} < \frac{P(A) \cdot P(B)}{P(A)} = P(B)$ .

**2.4.4**  $P(E|A \cup B) = \frac{P(E \cap (A \cup B))}{P(A \cup B)} = \frac{P(E)}{P(A \cup B)} = \frac{P(A \cup B) - P(A \cap B)}{P(A \cup B)} = \frac{0.4 - 0.1}{0.4} = \frac{3}{4}$ .

**2.4.5** The answer would remain the same. Distinguishing only three family types does not make them equally likely; (girl, boy) families will occur twice as often as either (boy, boy) or (girl, girl) families.

**2.4.6**  $P(A \cup B) = 0.8$  and  $P(A \cup B) - P(A \cap B) = 0.6$ , so  $P(A \cap B) = 0.2$ .  
Also,  $P(A|B) = 0.6 = \frac{P(A \cap B)}{P(B)}$ , so  $P(B) = \frac{0.2}{0.6} = \frac{1}{3}$  and  $P(A) = 0.8 + 0.2 - \frac{1}{3} = \frac{2}{3}$ .

**2.4.7** Let  $R_i$  be the event that a red chip is selected on the  $i$ th draw,  $i = 1, 2$ .

Then  $P(\text{both are red}) = P(R_1 \cap R_2) = P(R_2 | R_1)P(R_1) = \frac{3}{4} \cdot \frac{1}{2} = \frac{3}{8}$ .

**2.4.8**  $P(A|B) = \frac{P(A \cap B)}{P(B)} = \frac{P(A) + P(B) - P(A \cup B)}{P(B)} = \frac{a + b - P(A \cup B)}{b}$ .

But  $P(A \cup B) \leq 1$ , so  $P(A|B) \geq \frac{a + b - 1}{b}$ .

**2.4.9** Let  $W_i$  be the event that a white chip is selected on the  $i$ th draw,  $i = 1, 2$ .

Then  $P(W_2|W_1) = \frac{P(W_1 \cap W_2)}{P(W_1)}$ . If both chips in the urn are white,  $P(W_1) = 1$ ;

if one is white and one is black,  $P(W_1) = \frac{1}{2}$ .

Since each chip distribution is equally likely,  $P(W_1) = 1 \cdot \frac{1}{2} + \frac{1}{2} \cdot \frac{1}{2} = \frac{3}{4}$ .

Similarly,  $P(W_1 \cap W_2) = 1 \cdot \frac{1}{2} + \frac{1}{4} \cdot \frac{1}{2} = \frac{5}{8}$ , so  $P(W_2|W_1) = \frac{5/8}{3/4} = \frac{5}{6}$ .

**2.4.10**  $P[(A \cap B) | (A \cup B)^c] = \frac{P[(A \cap B) \cap (A \cup B)^c]}{P[(A \cup B)^c]} = \frac{P(\emptyset)}{P[(A \cup B)^c]} = 0$

**2.4.11** (a)  $P(A^c \cap B^c) = 1 - P(A \cup B) = 1 - [P(A) + P(B) - P(A \cap B)] = 1 - [0.65 + 0.55 - 0.25] = 0.05$

- (b)  $P[(A^C \cap B) \cup (A \cap B^C)] = P(A^C \cap B) + P(A \cap B^C) =$   
 $[P(A) - P(A \cap B)] + [P(B) - P(A \cap B)] = [0.65 - 0.25] + [0.55 - 0.25] = 0.70$
- (c)  $P(A \cup B) = 0.95$
- (d)  $P[(A \cap B)^C] = 1 - P(A \cap B) = 1 - 0.25 = 0.75$
- (e)  $P\{[(A^C \cap B) \cup (A \cap B^C)] | A \cup B\} = \frac{P[(A^C \cap B) \cup (A \cap B^C)]}{P(A \cup B)} = 0.70/0.95 = 70/95$
- (f)  $P(A \cap B) | A \cup B = P(A \cap B)/P(A \cup B) = 0.25/0.95 = 25/95$
- (g)  $P(B|A^C) = P(A^C \cap B)/P(A^C) = [P(B) - P(A \cap B)]/[1 - P(A)] = [0.55 - 0.25]/[1 - 0.65] = 30/35$

- 2.4.12**  $P(\text{No. of heads} \geq 2 | \text{No. of heads} \leq 2)$   
 $= P(\text{No. of heads} \geq 2 \text{ and No. of heads} \leq 2)/P(\text{No. of heads} \leq 2)$   
 $= P(\text{No. of heads} = 2)/P(\text{No. of heads} \leq 2) = (3/8)/(7/8) = 3/7$
- 2.4.13**  $P(\text{first die} \geq 4 | \text{sum} = 8) = P(\text{first die} \geq 4 \text{ and sum} = 8)/P(\text{sum} = 8)$   
 $= P(\{(4, 4), (5, 3), (6, 2)\})/P(\{(2, 6), (3, 5), (4, 4), (5, 3), (6, 2)\}) = 3/5$
- 2.4.14** There are 4 ways to choose three aces (count which one is left out). There are 48 ways to choose the card that is not an ace, so there are  $4 \times 48 = 192$  sets of cards where exactly three are aces. That gives 193 sets where there are at least three aces. The conditional probability is  $(1/270,725)/(193/270,725) = 1/193$ .
- 2.4.15** First note that  $P(A \cup B) = 1 - P[(A \cup B)^C] = 1 - 0.2 = 0.8$ .  
Then  $P(B) = P(A \cup B) - P(A \cap B^C) - P(A \cap B) = 0.8 - 0.3 - 0.1 = 0.5$ .  
Finally  $P(A|B) = P(A \cap B)/P(B) = 0.1/0.5 = 1/5$
- 2.4.16**  $P(A|B) = 0.5$  implies  $P(A \cap B) = 0.5P(B)$ .  $P(B|A) = 0.4$  implies  $P(A \cap B) = (0.4)P(A)$ .  
Thus,  $0.5P(B) = 0.4P(A)$  or  $P(B) = 0.8P(A)$ .  
Then,  $0.9 = P(A) + P(B) = P(A) + 0.8P(A)$  or  $P(A) = 0.9/1.8 = 0.5$ .
- 2.4.17**  $P[(A \cap B)^C] = P[(A \cup B)^C] + P(A \cap B^C) + P(A^C \cap B) = 0.2 + 0.1 + 0.3 = 0.6$   
 $P(A \cup B | (A \cap B)^C) = P[(A \cap B^C) \cup (A^C \cap B)]/P((A \cap B)^C) = [0.1 + 0.3]/0.6 = 2/3$
- 2.4.18**  $P(\text{sum} \geq 8 | \text{at least one die shows 5})$   
 $= P(\text{sum} \geq 8 \text{ and at least one die shows 5})/P(\text{at least one die shows 5})$   
 $= P(\{(5, 3), (5, 4), (5, 6), (3, 5), (4, 5), (6, 5), (5, 5)\})/(11/36) = 7/11$
- 2.4.19**  $P(\text{Outandout wins} | \text{Australian Doll and Dusty Stake don't win})$   
 $= P(\text{Outandout wins and Australian Doll and Dusty Stake don't win})/P(\text{Australian Doll and Dusty Stake don't win}) = 0.20/0.55 = 20/55$
- 2.4.20** Suppose the guard will randomly choose to name Bob or Charley if they are the two to go free. Then the probability the guard will name Bob, for example, is  $P(\text{Andy, Bob}) + (1/2)P(\text{Bob, Charley}) = 1/3 + (1/2)(1/3) = 1/2$ .  
The probability Andy will go free given the guard names Bob is  $P(\text{Andy, Bob})/P(\text{Guard names Bob}) = (1/3)/(1/2) = 2/3$ . A similar argument holds for the guard naming Charley. Andy's concern is not justified.

$$2.4.21 \quad P(BBRWW) = P(B)P(B|B)P(R|BB)P(W|BBR)P(W|BBRW) = \frac{4}{15} \cdot \frac{3}{14} \cdot \frac{5}{13} \cdot \frac{6}{12} \cdot \frac{5}{11} = 0.0050$$

$$P(2, 6, 4, 9, 13) = \frac{1}{15} \cdot \frac{1}{14} \cdot \frac{1}{13} \cdot \frac{1}{12} \cdot \frac{1}{11} = \frac{1}{360,360}.$$

$$2.4.22 \quad \text{Let } K_i \text{ be the event that the } i\text{th key tried opens the door, } i = 1, 2, \dots, n. \text{ Then } P(\text{door opens first time with 3rd key}) = P(K_1^C \cap K_2^C \cap K_3) = P(K_1^C) \cdot P(K_2^C | K_1^C) \cdot P(K_3 | K_1^C \cap K_2^C) \\ = \frac{n-1}{n} \cdot \frac{n-2}{n-1} \cdot \frac{1}{n-2} = \frac{1}{n}.$$

$$2.4.23 \quad (a) \text{ The complementary event is that the team loses three or four games. Assume the games are independent. The probability of the event is } (0.6)(0.50)(0.6)(0.3) + (0.4)(0.50)(0.6)(0.3) + (0.4)(0.50)(0.4)(0.3) + (0.4)(0.50)(0.6)(0.7) \\ + (0.4)(0.50)(0.6)(0.3) = 0.234.$$

The probability of a bowl appearance is  $1 - 0.234 = 0.766$ .

$$(b) \text{ Let } A_k = \text{probability team wins exactly } k \text{ games, } k = 3, 4.$$

$$\text{Then } P(A_4 | A_3 \cup A_4) = \frac{P[A_4 \cap (A_3 \cup A_4)]}{P(A_3 \cup A_4)} = \frac{P[(A_4 \cap A_3) \cup A_4]}{P(A_3 \cup A_4)} = \frac{P(\emptyset) \cup P(A_4)}{P(A_3 \cup A_4)}$$

But this does not equal  $P(A_4)$ .

$$(c) \text{ Yes, the two events are independent.}$$

$$2.4.24 \quad (1/2)(1/2)(1/2)(2/3)(3/4) = 1/16$$

$$2.4.25 \quad \text{Let } A_i \text{ be the event "Bearing came from supplier } i", i = 1, 2, 3. \text{ Let } B \text{ be the event "Bearing in toy manufacturer's inventory is defective."} \\ \text{Then } P(A_1) = 0.5, P(A_2) = 0.3, P(A_3) = 0.2 \text{ and } P(B|A_1) = 0.02, P(B|A_2) = 0.03, P(B|A_3) = 0.04 \\ \text{Combining these probabilities according to Theorem 2.4.1 gives} \\ P(B) = (0.02)(0.5) + (0.03)(0.3) + (0.04)(0.2) = 0.027 \\ \text{meaning that the manufacturer can expect 2.7\% of her ball-bearing stock to be defective.}$$

$$2.4.26 \quad \text{Let } B \text{ be the event that the face (or sum of faces) equals 6. Let } A_1 \text{ be the event that a Head comes up and } A_2, \text{ the event that a Tail comes up. Then } P(B) = P(B|A_1)P(A_1) + P(B|A_2)P(A_2) \\ = \frac{1}{6} \cdot \frac{1}{2} + \frac{5}{36} \cdot \frac{1}{2} = 0.15.$$

$$2.4.27 \quad \text{Let } B \text{ be the event that the countries go to war. Let } A \text{ be the event that terrorism increases.} \\ \text{Then } P(B) = P(B|A)P(A) + P(B|A^C)P(A^C) = (0.65)(0.30) + (0.05)(0.70) = 0.23.$$

$$2.4.28 \quad \text{Let } B \text{ be the event that a donation is received; let } A_1, A_2, \text{ and } A_3 \text{ denote the events that the call is placed to Belle Meade, Oak Hill, and Antioch, respectively.}$$

$$\text{Then } P(B) = \sum_{i=1}^3 P(B|A_i)P(A_i) = (0.60) \cdot \frac{1000}{4000} + (0.55) \cdot \frac{1000}{4000} + (0.35) \cdot \frac{2000}{4000} = 0.46.$$

$$2.4.29 \quad \text{Let } B \text{ denote the event that the person interviewed answers truthfully, and let } A \text{ be the event that the person interviewed is a man.} \\ \text{Then } P(B) = P(B|A)P(A) + P(B|A^C)P(A^C) = (0.78)(0.47) + (0.63)(0.53) = 0.70.$$

- 2.4.30** Let  $B$  be the event that a red chip is ultimately drawn from Urn I. Let  $A_{RW}$ , for example, denote the event that a red is transferred from Urn I and a white is transferred from Urn II. Then  $P(B) = P(B|A_{RR})P(A_{RR}) + P(B|A_{RW})P(A_{RW}) + P(B|A_{WR})P(A_{WR}) + P(B|A_{WW})P(A_{WW})$   

$$= \frac{3}{4} \left( \frac{3}{4} \cdot \frac{2}{4} \right) + \frac{2}{4} \left( \frac{3}{4} \cdot \frac{2}{4} \right) + 1 \left( \frac{1}{4} \cdot \frac{2}{4} \right) + \frac{3}{4} \left( \frac{1}{4} \cdot \frac{2}{4} \right) = \frac{11}{16}.$$
- 2.4.31** Let  $B$  denote the event that someone will test positive, and let  $A$  denote the event that someone is infected. Then  

$$P(B) = P(B|A)P(A) + P(B|A^C)P(A^C) = (0.999)(0.0001) + (0.0001)(0.9999) = 0.00019989.$$
- 2.4.32** The optimal allocation has 1 white chip in one urn and the other 19 chips (9 white and 10 black) in the other urn. Then  $P(\text{white is drawn}) = 1 \cdot \frac{1}{2} + \frac{9}{19} \cdot \frac{1}{2} = 0.74.$
- 2.4.33** Let  $D_i$  be the probability that Democrat  $i$  wins the primary,  $i = 1, 2, 3$ .  

$$P(R \text{ wins}) = P(R|D_1)P(D_1) + P(R|D_2)P(D_2) + P(R|D_3)P(D_3)$$

$$= (0.40)(0.35) + (0.35)(0.40) + (0.60)(0.25) = 0.43$$
- 2.4.34** Since the identities of the six chips drawn are not known, their selection does not affect any probability associated with the seventh chip. Therefore,  

$$P(\text{seventh chip drawn is red}) = P(\text{first chip drawn is red}) = \frac{40}{100}.$$
- 2.4.35** No. Let  $B$  denote the event that the person calling the toss is correct. Let  $A_H$  be the event that the coin comes up Heads and let  $A_T$  be the event that the coin comes up Tails.  
 Then  $P(B) = P(B|A_H)P(A_H) + P(B|A_T)P(A_T) = (0.7) \left( \frac{1}{2} \right) + (0.3) \left( \frac{1}{2} \right) = \frac{1}{2}.$
- 2.4.36** Let  $B$  be the event of a guilty verdict; let  $A$  be the event that the defense can discredit the police. Then  $P(B) = P(B|A)P(A) + P(B|A^C)P(A^C) = 0.15(0.70) + 0.80(0.30) = 0.345$
- 2.4.37** Let  $A_1$  be the event of a 3.5-4.0 GPA;  $A_2$ , of a 3.0-3.5 GPA; and  $A_3$ , of a GPA less than 3.0. If  $B$  is the event of getting into medical school, then  

$$P(B) = P(B|A_1)P(A_1) + P(B|A_2)P(A_2) + P(B|A_3)P(A_3) = (0.8)(0.25) + (0.5)(0.35) + (0.1)(0.40)$$

$$= 0.415$$
- 2.4.38** Let  $B$  be the event of early release; let  $A$  be the event that the prisoner is related to someone on the governor's staff.  
 Then  $P(B) = P(B|A)P(A) + P(B|A^C)P(A^C) = (0.90)(0.40) + (0.01)(0.60) = 0.366$
- 2.4.39** Let  $A_1$  be the event of being a Humanities major;  $A_2$ , of being a Natural Science major;  $A_3$ , of being a History major; and  $A_4$ , of being a Social Science major. If  $B$  is the event of a male student, then  $P(B) = P(B|A_1)P(A_1) + P(B|A_2)P(A_2) + P(B|A_3)P(A_3) + P(B|A_4)P(A_4)$   

$$= (0.40)(0.4) + (0.85)(0.1) + (0.55)(0.3) + (0.25)(0.2) = 0.46$$
- 2.4.40** Let  $B$  denote the event that the chip drawn from Urn II is red; let  $A_R$  and  $A_W$  denote the events that the chips transferred are red and white, respectively.

$$\text{Then } P(A_W | B) = \frac{P(B | A_W)P(A_W)}{P(B | A_R)P(A_R) + P(B | A_W)P(A_W)} = \frac{(2/4)(2/3)}{(3/4)(1/3) + (2/4)(2/3)} = \frac{4}{7}$$

**2.4.41** Let  $A_i$  be the event that Urn  $i$  is chosen,  $i = \text{I, II, III}$ . Then,  $P(A_i) = 1/3$ ,  $i = \text{I, II, III}$ . Suppose  $B$  is the event a red chip is drawn. Note that  $P(B|A_1) = 3/8$ ,  $P(B|A_2) = 1/2$  and  $P(B|A_3) = 5/8$ .

$$\begin{aligned} P(A_3 | B) &= \frac{P(B | A_3)P(A_3)}{P(B | A_1)P(A_1) + P(B | A_2)P(A_2) + P(B | A_3)P(A_3)} \\ &= \frac{(5/8)(1/3)}{(3/8)(1/3) + (1/2)(1/3) + (5/8)(1/3)} = 5/12. \end{aligned}$$

**2.4.42** If  $B$  is the event that the warning light flashes and  $A$  is the event that the oil pressure is low, then

$$P(A|B) = \frac{P(B | A)P(A)}{P(B | A)P(A) + P(B | A^c)P(A^c)} = \frac{(0.99)(0.10)}{(0.99)(0.10) + (0.02)(0.90)} = 0.85$$

**2.4.43** Let  $B$  be the event that the basement leaks, and let  $A_T$ ,  $A_W$ , and  $A_H$  denote the events that the house was built by Tara, Westview, and Hearthstone, respectively. Then  $P(B|A_T) = 0.60$ ,  $P(B|A_W) = 0.50$ , and  $P(B|A_H) = 0.40$ . Also,  $P(A_T) = 2/11$ ,  $P(A_W) = 3/11$ , and  $P(A_H) = 6/11$ . Applying Bayes' rule to each of the builders shows that  $P(A_T|B) = 0.24$ ,  $P(A_W|B) = 0.29$ , and  $P(A_H|B) = 0.47$ , implying that Hearthstone is the most likely contractor.

**2.4.44** Let  $B$  denote the event that Francesca passed, and let  $A_X$  and  $A_Y$  denote the events that she was enrolled in Professor  $X$ 's section and Professor  $Y$ 's section, respectively. Since  $P(B|A_X) = 0.85$ ,  $P(B|A_Y) = 0.60$ ,  $P(A_X) = 0.4$ , and  $P(A_Y) = 0.6$ ,

$$P(A_X|B) = \frac{(0.85)(0.4)}{(0.85)(0.4) + (0.60)(0.6)} = 0.486$$

**2.4.45** Let  $B$  denote the event that a check bounces, and let  $A$  be the event that a customer wears sunglasses. Then  $P(B|A) = 0.50$ ,  $P(B|A^c) = 1 - 0.98 = 0.02$ , and  $P(A) = 0.10$ , so

$$P(A|B) = \frac{(0.50)(0.10)}{(0.50)(0.10) + (0.02)(0.90)} = 0.74$$

**2.4.46** Let  $B$  be the event that Basil dies, and define  $A_1$ ,  $A_2$ , and  $A_3$  to be the events that he ordered cherries flambe, chocolate mousse, or no dessert, respectively. Then  $P(B|A_1) = 0.60$ ,  $P(B|A_2) = 0.90$ ,  $P(B|A_3) = 0$ ,  $P(A_1) = 0.50$ ,  $P(A_2) = 0.40$ , and  $P(A_3) = 0.10$ . Comparing  $P(A_1|B)$  and  $P(A_2|B)$  suggests that Margo should be considered the prime suspect:

$$P(A_1|B) = \frac{(0.60)(0.50)}{(0.60)(0.50) + (0.90)(0.40) + (0)(0.10)} = 0.45$$

$$P(A_2|B) = \frac{(0.90)(0.40)}{(0.60)(0.50) + (0.90)(0.40) + (0)(0.10)} = 0.55$$

**2.4.47** Define  $B$  to be the event that Josh answers a randomly selected question correctly, and let  $A_1$  and  $A_2$  denote the events that he was 1) unprepared for the question and 2) prepared for the question, respectively. Then  $P(B|A_1) = 0.20$ ,  $P(B|A_2) = 1$ ,  $P(A_2) = p$ ,  $P(A_1) = 1 - p$ , and

$$P(A_2|B) = 0.92 = \frac{P(B | A_2)P(A_2)}{P(B | A_1)P(A_1) + P(B | A_2)P(A_2)} = \frac{1 \cdot p}{(0.20)(1 - p) + (1 \cdot p)}$$

which implies that  $p = 0.70$  (meaning that Josh was prepared for  $(0.70)(20) = 14$  of the questions).

- 2.4.48** Let  $B$  denote the event that the program diagnoses the child as abused, and let  $A$  be the event that the child is abused. Then  $P(A) = 1/90$ ,  $P(B|A) = 0.90$ , and  $P(B|A^C) = 0.03$ , so

$$P(A|B) = \frac{(0.90)(1/90)}{(0.90)(1/90) + (0.03)(89/90)} = 0.25$$

If  $P(A) = 1/1000$ ,  $P(A|B) = 0.029$ ; if  $P(A) = 1/50$ ,  $P(A|B) = 0.38$ .

- 2.4.49** Let  $A_1$  be the event of being a Humanities major;  $A_2$ , of being a History and Culture major; and  $A_3$ , of being a Science major. If  $B$  is the event of being a woman, then

$$P(A_2|B) = \frac{(0.45)(0.5)}{(0.75)(0.3) + (0.45)(0.5) + (0.30)(0.2)} = 225/510$$

- 2.4.50** Let  $B$  be the event that a 1 is received. Let  $A$  be the event that a 1 was sent. Then

$$P(A^C|B) = \frac{(0.10)(0.3)}{(0.95)(0.7) + (0.10)(0.3)} = 30/695$$

- 2.4.51** Let  $B$  be the event that Zach's girlfriend responds promptly. Let  $A$  be the event that Zach sent an e-mail, so  $A^C$  is the event of leaving a message. Then

$$P(A|B) = \frac{(0.8)(2/3)}{(0.8)(2/3) + (0.9)(1/3)} = 16/25$$

- 2.4.52** Let  $A$  be the event that the shipment came from Warehouse  $A$  with events  $B$  and  $C$  defined similarly. Let  $D$  be the event of a complaint.

$$\begin{aligned} P(C|D) &= \frac{P(D|C)P(C)}{P(D|A)P(A) + P(D|B)P(B) + P(D|C)P(C)} \\ &= \frac{(0.02)(0.5)}{(0.03)(0.3) + (0.05)(0.2) + (0.02)(0.5)} = 10/29 \end{aligned}$$

- 2.4.53** Let  $A_i$  be the event that Drawer  $i$  is chosen,  $i = 1, 2, 3$ . If  $B$  is the event a silver coin is

selected, then  $P(A_3|B) = \frac{(0.5)(1/3)}{(0)(1/3) + (1)(1/3) + (0.5)(1/3)} = 1/3$

- 2.4.54** Use for comparison the following quantities:

Young:  $20(0.35) = 7$ ; Middle-aged:  $50(0.15) = 7.5$ ; Elderly  $30(0.25) = 7.5$ . Thus, it is equally likely that the person is either middle-aged or elderly.

## Section 2.5: Independence

- 2.5.1** (a) No, because  $P(A \cap B) > 0$ .

(b) No, because  $P(A \cap B) = 0.2 \neq P(A) \cdot P(B) = (0.6)(0.5) = 0.3$

(c)  $P(A^C \cup B^C) = P((A \cap B)^C) = 1 - P(A \cap B) = 1 - 0.2 = 0.8$ .

- 2.5.2** Let  $C$  and  $M$  be the events that Spike passes chemistry and mathematics, respectively. Since  $P(C \cap M) = 0.12 \neq P(C) \cdot P(M) = (0.35)(0.40) = 0.14$ ,  $C$  and  $M$  are not independent.

- $P(\text{Spike fails both}) = 1 - P(\text{Spike passes at least one}) = 1 - P(C \cup M)$   
 $= 1 - [P(C) + P(M) - P(C \cap M)] = 0.37.$
- 2.5.3**  $P(\text{one face is twice the other face}) = P((1, 2), (2, 1), (2, 4), (4, 2), (3, 6), (6, 3)) = \frac{6}{36}.$
- 2.5.4** Consider the probability of the complementary event that they have the same blood types:  
 $0.4^2 + 0.01^2 + 0.05^2 + 0.45^2 = 0.375.$   
 Then the probability they have different blood types is  $1 - 0.375 = 0.625.$
- 2.5.5**  $P(\text{Dana wins at least 1 game out of 2}) = 0.3$ , which implies that  $P(\text{Dana loses 2 games out of 2}) = 0.7.$  Therefore,  $P(\text{Dana wins at least 1 game out of 4}) = 1 - P(\text{Dana loses all 4 games})$   
 $= 1 - P(\text{Dana loses first 2 games and Dana loses second 2 games}) = 1 - (0.7)(0.7) = 0.51.$
- 2.5.6** Six equally-likely orderings are possible for any set of three distinct random numbers:  
 $x_1 < x_2 < x_3, x_1 < x_3 < x_2, x_2 < x_1 < x_3, x_2 < x_3 < x_1, x_3 < x_1 < x_2,$  and  $x_3 < x_2 < x_1.$  By inspection,  $P(A) = \frac{2}{6}$ , and  $P(B) = \frac{1}{6}$ , so  $P(A \cap B) = P(A) \cdot P(B) = \frac{1}{18}.$
- 2.5.7** (a) 1.  $P(A \cup B) = P(A) + P(B) - P(A \cap B) = 1/4 + 1/8 + 0 = 3/8$   
 2.  $P(A \cup B) = P(A) + P(B) - P(A)P(B) = 1/4 + 1/8 - (1/4)(1/8) = 11/32$   
 (b) 1.  $P(A|B) = \frac{P(A \cap B)}{P(B)} = \frac{0}{P(B)} = 0$   
 2.  $P(A|B) = \frac{P(A \cap B)}{P(B)} = \frac{P(A)P(B)}{P(B)} = P(A) = 1/4$
- 2.5.8** (a)  $P(A \cup B \cup C) = P(A) + P(B) + P(C) - P(A)P(B) - P(A)P(C) - P(B)P(C) + P(A)P(B)P(C)$   
 (b)  $P(A \cup B \cup C) = 1 - P[(A \cup B \cup C)^c] = 1 - P(A^c \cap B^c \cap C^c) = 1 - P(A^c)P(B^c)P(C^c)$
- 2.5.9** Let  $A_i$  be the event of  $i$  heads in the first two tosses,  $i = 0, 1, 2.$  Let  $B_i$  be the event of  $i$  heads in the last two tosses,  $i = 0, 1, 2.$  The  $A$ 's and  $B$ 's are independent. The event of interest is  $(A_0 \cap B_0) \cup (A_1 \cap B_1) \cup (A_2 \cap B_2)$  and  $P[(A_0 \cap B_0) \cup (A_1 \cap B_1) \cup (A_2 \cap B_2)]$   
 $= P(A_0)P(B_0) + P(A_1)P(B_1) + P(A_2)P(B_2) = (1/4)(1/4) + (1/2)(1/2) + (1/4)(1/4) = 6/16$
- 2.5.10**  $A$  and  $B$  are disjoint, so they cannot be independent.
- 2.5.11** Equation 2.5.3:  $P(A \cap B \cap C) = P(\{1, 3\}) = 1/36 = (2/6)(3/6)(6/36) = P(A)P(B)P(C)$   
 Equation 2.5.4:  $P(B \cap C) = P(\{1, 3\}, (5, 6)) = 2/36 \neq (3/6)(6/36) = P(B)P(C)$
- 2.5.12** Equation 2.5 3:  $P(A \cap B \cap C) = P(\{2, 4, 10, 12\}) = 4/36 \neq (1/2)(1/2)(1/2) = P(A)P(B)P(C)$   
 Equation 2.5.4:  $P(A \cap B) = P(\{2, 4, 10, 12, 24, 26, 32, 34, 36\}) = 9/36 = 1/4 = (1/2)(1/2) = P(A)P(B)$   
 $P(A \cap C) = P(\{1, 2, 3, 4, 5, 10, 11, 12, 13\}) = 9/36 = 1/4 = (1/2)(1/2) = P(A)P(C)$   
 $P(B \cap C) = P(\{2, 4, 6, 8, 10, 12, 14, 16, 18\}) = 9/36 = 1/4 = (1/2)(1/2) = P(A)P(C)$
- 2.5.13** 11 [= 6 verifications of the form  $P(A_i \cap A_j) = P(A_i) \cdot P(A_j)$  + 4 verifications of the form  $P(A_i \cap A_j \cap A_k) = P(A_i) \cdot P(A_j) \cdot P(A_k)$  + 1 verification that  $P(A_1 \cap A_2 \cap A_3 \cap A_4) = P(A_1) \cdot P(A_2) \cdot P(A_3) \cdot P(A_4)$ ].

**2.5.14**  $P(A) = \frac{3}{6}, P(B) = \frac{2}{6}, P(C) = \frac{6}{36}, P(A \cap B) = \frac{6}{36}, P(A \cap C) = \frac{3}{36}, P(B \cap C) = \frac{2}{36}$ , and  $P(A \cap B \cap C) = \frac{1}{36}$ . It follows that  $A, B$ , and  $C$  are mutually independent because

$$P(A \cap B \cap C) = \frac{1}{36} = P(A) \cdot P(B) \cdot P(C) = \frac{3}{6} \cdot \frac{2}{6} \cdot \frac{6}{36}, P(A \cap B) = \frac{6}{36} = P(A) \cdot P(B) = \frac{3}{6} \cdot \frac{2}{6},$$

$$P(A \cap C) = \frac{3}{36} = P(A) \cdot P(C) = \frac{3}{6} \cdot \frac{6}{36}, \text{ and } P(B \cap C) = \frac{2}{36} = P(B) \cdot P(C) = \frac{2}{6} \cdot \frac{6}{36}.$$

**2.5.15**  $P(A \cap B \cap C) = 0$  (since the sum of two odd numbers is necessarily even)  $\neq P(A) \cdot P(B) \cdot P(C) > 0$ , so  $A, B$ , and  $C$  are not mutually independent. However,  $P(A \cap B) = \frac{9}{36}$

$$= P(A) \cdot P(B) = \frac{3}{6} \cdot \frac{3}{6}, P(A \cap C) = \frac{9}{36} = P(A) \cdot P(C) = \frac{3}{6} \cdot \frac{18}{36}, \text{ and } P(B \cap C) = \frac{9}{36} = P(B) \cdot P(C) = \frac{3}{6} \cdot \frac{18}{36},$$

so  $A, B$ , and  $C$  are pairwise independent.

**2.5.16** Let  $R_i$  and  $G_i$  be the events that the  $i$ th light is red and green, respectively,  $i = 1, 2, 3, 4$ . Then  $P(R_1) = P(R_2) = \frac{1}{3}$  and  $P(R_3) = P(R_4) = \frac{1}{2}$ . Because of the considerable distance between the intersections, what happens from light to light can be considered independent events.

$$P(\text{driver stops at least 3 times}) = P(\text{driver stops exactly 3 times}) + P(\text{driver stops all 4 times})$$

$$= P((R_1 \cap R_2 \cap R_3 \cap G_4) \cup (R_1 \cap R_2 \cap G_3 \cap R_4) \cup (R_1 \cap G_2 \cap R_3 \cap R_4) \cup (G_1 \cap R_2 \cap R_3 \cap R_4) \cup (R_1 \cap R_2 \cap R_3 \cap R_4))$$

$$= \left(\frac{1}{3}\right)\left(\frac{1}{3}\right)\left(\frac{1}{2}\right)\left(\frac{1}{2}\right) + \left(\frac{1}{3}\right)\left(\frac{1}{3}\right)\left(\frac{1}{2}\right)\left(\frac{1}{2}\right) + \left(\frac{1}{3}\right)\left(\frac{2}{3}\right)\left(\frac{1}{2}\right)\left(\frac{1}{2}\right) + \left(\frac{2}{3}\right)\left(\frac{1}{3}\right)\left(\frac{1}{2}\right)\left(\frac{1}{2}\right) + \left(\frac{1}{3}\right)\left(\frac{1}{3}\right)\left(\frac{1}{2}\right)\left(\frac{1}{2}\right) = \frac{7}{36}.$$

**2.5.17** Let  $M, L$ , and  $G$  be the events that a student passes the mathematics, language, and general knowledge tests, respectively. Then  $P(M) = \frac{6175}{9500}, P(L) = \frac{7600}{9500}$ , and  $P(G) = \frac{8075}{9500}$ .

$$P(\text{student fails to qualify}) = P(\text{student fails at least one exam})$$

$$= 1 - P(\text{student passes all three exams}) = 1 - P(M \cap L \cap G) = 1 - P(M) \cdot P(L) \cdot P(G) = 0.56.$$

**2.5.18** Let  $A_i$  denote the event that switch  $A_i$  closes,  $i = 1, 2, 3, 4$ . Since the  $A_i$ 's are independent events,  $P(\text{circuit is completed}) =$

$$P((A_1 \cap A_2) \cup (A_3 \cap A_4)) = P(A_1 \cap A_2) + P(A_3 \cap A_4) - P((A_1 \cap A_2) \cap (A_3 \cap A_4)) = 2p^2 - p^4.$$

**2.5.19** Let  $p$  be the probability of having a winning game card. Then  $0.32 = P(\text{winning at least once in 5 tries}) = 1 - P(\text{not winning in 5 tries}) = 1 - (1 - p)^5$ , so  $p = 0.074$

**2.5.20** Let  $A_H$ ,  $A_T$ ,  $B_H$ ,  $B_T$ ,  $C_H$ , and  $C_T$  denote the events that players  $A$ ,  $B$ , and  $C$  throw heads and tails on individual tosses. Then  $P(A \text{ throws first head}) = P(A_H \cup (A_T \cap B_T \cap C_T \cap A_H) \cup \dots)$

$$= \frac{1}{2} + \frac{1}{2} \left( \frac{1}{8} \right) + \frac{1}{2} \left( \frac{1}{8} \right)^2 + \dots = \frac{1}{2} \left( \frac{1}{1 - 1/8} \right) = \frac{4}{7}.$$

Similarly,  $P(B \text{ throws first head}) = P((A_T \cap B_H) \cup (A_T \cap B_T \cap C_T \cap A_T \cap B_H) \cup \dots)$

$$= \frac{1}{4} + \frac{1}{4} \left( \frac{1}{8} \right) + \frac{1}{4} \left( \frac{1}{8} \right)^2 + \dots = \frac{1}{4} \left( \frac{1}{1 - 1/8} \right) = \frac{2}{7}.$$

$$P(C \text{ throws first head}) = 1 - \frac{4}{7} - \frac{2}{7} = \frac{1}{7}.$$

**2.5.21**  $P(\text{at least one child becomes adult}) = 1 - P(\text{no child becomes adult}) = 1 - 0.8^n$ .

Then  $1 - 0.8^n \geq 0.75$  implies  $n \geq \frac{\ln 0.25}{\ln 0.8}$  or  $n \geq 6.2$ , so take  $n = 7$ .

**2.5.22**  $P(\text{at least one viewer can name actor}) = 1 - P(\text{no viewer can name actor}) = 1 - (0.85)^{10} = 0.80$ .

**2.5.23** Let  $B$  be the event that no heads appear, and let  $A_i$  be the event that  $i$  coins are tossed,

$$i = 1, 2, \dots, 6. \text{ Then } P(B) = \sum_{i=1}^6 P(B | A_i) P(A_i) = \frac{1}{2} \left( \frac{1}{6} \right) + \left( \frac{1}{2} \right)^2 \left( \frac{1}{6} \right) + \dots + \left( \frac{1}{2} \right)^6 \left( \frac{1}{6} \right) = \frac{63}{384}.$$

**2.5.24**  $P(\text{at least one red chip is drawn from at least one urn}) = 1 - P(\text{all chips drawn are white})$

$$= 1 - \left( \frac{4}{7} \right)^r \cdot \left( \frac{4}{7} \right)^r \cdots \left( \frac{4}{7} \right)^r = 1 - \left( \frac{4}{7} \right)^{rm}.$$

**2.5.25**  $P(\text{at least one double six in } n \text{ throws}) = 1 - P(\text{no double sixes in } n \text{ throws}) = 1 - \left( \frac{35}{36} \right)^n$ . By trial and error, the smallest  $n$  for which  $P(\text{at least one double six in } n \text{ throws})$  exceeds 0.50 is 25 [ $1 - \left( \frac{35}{36} \right)^{24} = 0.49$ ;  $1 - \left( \frac{35}{36} \right)^{25} = 0.51$ ].

**2.5.26** Let  $A$  be the event that a sum of 8 appears before a sum of 7. Let  $B$  be the event that a sum of 8 appears on a given roll and let  $C$  be the event that the sum appearing on a given roll is

neither 7 nor 8. Then  $P(B) = \frac{5}{36}$ ,  $P(C) = \frac{25}{36}$ , and  $P(A) = P(B) + P(C)P(B) + P(C)P(C)P(B)$

$$+ \dots = \frac{5}{36} + \frac{25}{36} \frac{5}{36} + \left( \frac{25}{36} \right)^2 \frac{5}{36} + \dots = \frac{5}{36} \sum_{k=0}^{\infty} \left( \frac{25}{36} \right)^k = \frac{5}{36} \left( \frac{1}{1 - 25/36} \right) = \frac{5}{11}.$$

**2.5.27** Let  $W$ ,  $B$ , and  $R$  denote the events of getting a white, black and red chip, respectively, on a given draw. Then  $P(\text{white appears before red}) = P(W \cup (B \cap W) \cup (B \cap B \cap W) \cup \dots)$

$$= \frac{w}{w+b+r} + \frac{b}{w+b+r} \cdot \frac{w}{w+b+r} + \left( \frac{b}{w+b+r} \right)^2 \cdot \frac{w}{w+b+r} + \dots$$

$$= \frac{w}{w+b+r} \cdot \left( \frac{1}{1 - b/(w+b+r)} \right) = \frac{w}{w+r}.$$

- 2.5.28**  $P(B|A_1) = 1 - P(\text{all } m \text{ I-teams fail}) = 1 - (1 - r)^m$ ; similarly,  $P(B|A_2) = 1 - (1 - r)^{n-m}$ . From Theorem 2.4.1,  $P(B) = [1 - (1 - r)^m]p + [1 - (1 - r)^{n-m}](1 - p)$ . Treating  $m$  as a continuous variable and differentiating  $P(B)$  gives

$$\frac{dP(B)}{dm} = -p(1 - r)^m \cdot \ln(1 - r) + (1 - p)(1 - r)^{n-m} \cdot \ln(1 - r). \text{ Setting } \frac{dP(B)}{dm} = 0 \text{ implies that}$$

$$m = \frac{n}{2} + \frac{\ln[(1 - p)/p]}{2 \ln(1 - r)}.$$

- 2.5.29**  $P(\text{at least one four}) = 1 - P(\text{no fours}) = 1 - (0.9)^n$ .  $1 - (0.9)^n \geq 0.7$  implies  $n = 12$

- 2.5.30** Let  $B$  be the event that all  $n$  tosses come up heads. Let  $A_1$  be the event that the coin has two heads, and let  $A_2$  be the event the coin is fair. Then

$$P(A_2 | B) = \frac{(1/2)^n (8/9)}{1(1/9) + (1/2)^n (8/9)} = \frac{8(1/2)^n}{1 + 8(1/2)^n}$$

By inspection, the limit of  $P(A_2 | B)$  as  $n$  goes to infinity is 0.

- 2.5.31** Assume the events that Stanley answers correctly from question to question are independent. (Is this a reasonable assumption?) The probability of answering at least one question on Final A is  $(0.45)(0.55) + (0.55)(0.45) + (0.45)(0.45) = 0.6975$

The probability of answering at least one question on Final B is  $(0.30)(0.70)(0.70) + ((0.70)(0.30)(0.70) + (0.30)(0.30)(0.70) + (0.30)(0.30)(0.70) + (0.30)(0.70)(0.30) + (0.70)(0.30)(0.30) + (0.30)(0.30)(0.30) = 0.657$

A simpler way to answer the question is to take the complement of the event that he answers none correctly. For Final A this is  $1 - (0.55)^2 = 0.6975$ .

For Final B this is  $1 - (0.70)^3 = 0.657$ .

With either method of solution, Stanley will be a bit better off taking Final A.

- 2.5.32** Take the complementary event that none of  $n$  switches opens. This probability is  $0.4^n$ . Then  $0.04^n \leq 0.02$  implies  $n \ln(0.04) \leq \ln(0.02)$  or  $n \geq \ln(0.02)/\ln(0.04) = 4.27$ . So the smallest  $n$  is 5.

## Section 2.6: Combinatorics

**2.6.1**  $2 \cdot 3 \cdot 2 \cdot 2 = 24$

**2.6.2**  $20 \cdot 9 \cdot 6 \cdot 20 = 21,600$

**2.6.3**  $3 \cdot 3 \cdot 5 = 45$ . Included will be aeu and cdx.

**2.6.4** (a)  $26^2 \cdot 10^4 = 6,760,000$

(b)  $26^2 \cdot 10 \cdot 9 \cdot 9 \cdot 8 \cdot 7 = 3,407,040$

(c) The total number of plates *with* four zeros is  $26 \cdot 26$ , so the total number *not* having four zeros must be  $26^2 \cdot 10^4 - 26^2 = 6,759,324$ .

- 2.6.5** There are 9 choices for the first digit (1 through 9), 9 choices for the second digit (0 + whichever eight digits are not appearing in the hundreds place), and 8 choices for the last digit. The number of admissible integers, then, is  $9 \cdot 9 \cdot 8 = 648$ . For the integer to be odd, the last digit must be either 1, 3, 5, 7, or 9. That leaves 8 choices for the first digit and 8 choices for the second digit, making a total of  $320 (= 8 \cdot 8 \cdot 5)$  odd integers.
- 2.6.6** For each topping, the customer has 2 choices: “add” or “do not add.” The eight available toppings, then, can produce a total of  $2^8 = 256$  different hamburgers.
- 2.6.7** The bases can be occupied in any of  $2^7$  ways (each of the seven can be either “empty” or “occupied”). Moreover, the batter can come to the plate facing any of five possible “out” situations (0 through 4). It follows that the number of base-out configurations is  $5 \cdot 2^7$ , or 640.
- 2.6.8**
- (a) There are 3 choices for the leading digit—7, 8, 9. There are 10 choices for each of the remaining eight places, for a total of  $3 \cdot 10^8$ . However, this count includes 7,000,000,000, so the answer is  $3 \cdot 10^8 - 1$ .
  - (b) Suppose the sequence starts with an even number. Counting 0 as even, there are 5 choices for each of the five even places and five choices for the four odd places, giving a total of  $5^9$ . But the same number occurs if the sequence starts with an odd number, so the answer is  $2 \cdot 5^9$ .
  - (c) There are  $5!$  choices for the first five digits. Then there are 6 choices for where the 2’s go, so the answer is  $5! \cdot 6$ .
- 2.6.9**  $4 \cdot 14 \cdot 6 + 4 \cdot 6 \cdot 5 + 14 \cdot 6 \cdot 5 + 4 \cdot 14 \cdot 5 = 1156$
- 2.6.10** There are two mutually exclusive sets of ways for the black and white keys to alternate—the black keys can be 1<sup>st</sup>, 3<sup>rd</sup>, 5<sup>th</sup>, and 7<sup>th</sup> notes in the melody, or the 2<sup>nd</sup>, 4<sup>th</sup>, 6<sup>th</sup>, and 8<sup>th</sup>. Since there are 5 black keys and 7 white keys, there are  $5 \cdot 7 \cdot 5 \cdot 7 \cdot 5 \cdot 7 \cdot 5 \cdot 7$  variations in the first set and  $7 \cdot 5 \cdot 7 \cdot 5 \cdot 7 \cdot 5 \cdot 7 \cdot 5$  in the second set. The total number of alternating melodies is the sum  $5^4 7^4 + 7^4 5^4 = 3,001,250$ .
- 2.6.11** The number of usable garage codes is  $2^8 - 1 = 255$ , because the “combination” where none of the buttons is pushed is inadmissible (recall Example 2.6.3). Five additional families can be added before the eight-button system becomes inadequate.
- 2.6.12** 4, because  $2^1 + 2^2 + 2^3 < 26$  but  $2^1 + 2^2 + 2^3 + 2^4 \geq 26$ .
- 2.6.13** In order to exceed 256, the binary sequence of coins must have a head in the ninth position and at least one head somewhere in the first eight tosses. The number of sequences satisfying those conditions is  $2^8 - 1$ , or 255. (The “1” corresponds to the sequences TTTTTTTH, whose value would not exceed 256.)
- 2.6.14** There are 3 choices for the vowel and 4 choices for the consonant, so there are  $3 \cdot 4 = 12$  choices, if order doesn’t matter. If we are taking ordered arrangements, then there are 24 ways, since each unordered selection can be written vowel first or consonant first.
- 2.6.15** There are  $1 \cdot 3$  ways if the ace of clubs is the first card and  $12 \cdot 4$  ways if it is not. The total is then  $3 + 12 \cdot 4 = 51$

- 2.6.16** Monica has  $3 \cdot 5 \cdot 2 = 30$  routes from Nashville to Anchorage, so there are  $30 \cdot 30 = 900$  choices of round trips.
- 2.6.17**  ${}_6P_3 = 6 \cdot 5 \cdot 4 = 120$
- 2.6.18**  ${}_4P_4 = 4! = 24$ ;  ${}_2P_2 \cdot {}_2P_2 = 4$
- 2.6.19**  $\log_{10}(30!) \doteq \log_{10}(\sqrt{2\pi}) + \left(30 + \frac{1}{2}\right) \log_{10}(30) - 30 \log_{10}e = 32.42246$ , which implies that  $30! \doteq 10^{32.42246} = 2.645 \times 10^{32}$ .
- 2.6.20**  ${}_9P_9 = 9! = 362,880$
- 2.6.21** There are 2 choices for the first digit, 6 choices for the middle digit, and 5 choices for the last digit, so the number of admissible integers that can be formed from the digits 1 through 7 is  $60 (= 2 \cdot 6 \cdot 5)$ .
- 2.6.22** (a)  ${}_8P_8 = 8! = 40,320$   
 (b) The men can be arranged in, say, the odd-numbered chairs in  ${}_4P_4$  ways; for each of those permutations, the women can be seated in the even-numbered chairs in  ${}_4P_4$  ways. But the men could also be in the even-numbered chairs. It follows that the total number of alternating seating arrangements is  ${}_4P_4 \cdot {}_4P_4 + {}_4P_4 \cdot {}_4P_4 = 1152$ .
- 2.6.23** There are 4 different sets of three semesters in which the electives could be taken. For each of those sets, the electives can be selected and arranged in  ${}_{10}P_3$  ways, which means that the number of possible schedules is  $4 \cdot {}_{10}P_3$ , or 2880.
- 2.6.24**  ${}_6P_6 = 720$ ;  ${}_6P_6 \cdot {}_6P_6 = 518,400$ ;  $6!6!2^6$  is the number of ways six male/female cheerleading teams can be positioned along a sideline if each team has the option of putting the male in front or the female in front;  $6!6!2^62^{12}$  is the number of arrangements subject to the conditions of the previous answer but with the additional option that each cheerleader can face either forwards or backwards.
- 2.6.25** The number of playing sequences where at least one side is out of order = total number of playing sequences – number of correct playing sequences =  ${}_6P_6 - 1 = 719$ .
- 2.6.26** (a) Each of the 4 men can be lined up in  ${}_4P_4 = 4! = 24$  ways; similarly for the women. The answer is  $24^2 = 576$ .  
 (b)  ${}_7P_7 = 7! = 5040$
- 2.6.27** There are  ${}_2P_2 = 2$  ways for you and a friend to be arranged,  ${}_8P_8$  ways for the other eight to be permuted, and six ways for you and a friend to be in consecutive positions in line. By the multiplication rule, the number of admissible arrangements is  ${}_2P_2 \cdot {}_8P_8 \cdot 6 = 483,840$ .
- 2.6.28** By inspection,  ${}_nP_1 = n$ . Assume that  ${}_nP_k = n(n-1) \cdots (n-k+1)$  is the number of ways to arrange  $k$  distinct objects without repetition. Notice that  $n-k$  options would be available for a  $(k+1)$ st object added to the sequences. By the multiplication rule, the number of sequences of length  $k+1$  must be  $n(n-1) \cdots (n-k+1)(n-k)$ . But the latter is the formula for  ${}_nP_{k+1}$ .

**2.6.29**  $(13!)^4$

**2.6.30** By definition,  $(n + 1)! = (n + 1) \cdot n!$ ; let  $n = 0$ .

**2.6.31**  ${}_9P_2 \cdot {}_4C_1 = 288$

**2.6.32** Two people between them:  $4 \cdot 2 \cdot 5! = 960$   
 Three people between them:  $3 \cdot 2 \cdot 5! = 720$   
 Four people between them:  $2 \cdot 2 \cdot 5! = 480$   
 Five people between them:  $1 \cdot 2 \cdot 5! = 240$   
 Total number of ways: 2400

**2.6.33** (a)  $(4!)(5!) = 2800$   
 (b)  $6(4!)(5!) = 17,280$   
 (c)  $(4!)(5!) = 2880$   
 (d)  $\binom{9}{4} (2)(5!) = 30,240$

**2.6.34** TENNESSEE can be permuted in  $\frac{9!}{4!2!2!1!} = 3780$  ways;  
 FLORIDA can be permuted in  $7! = 5040$  ways.

**2.6.35** If the first digit is a 4, the remaining six digits can be arranged in  $\frac{6!}{3!(1!)^3} = 120$  ways; if the first digit is a 5, the remaining six digits can be arranged in  $\frac{6!}{2!2!(1!)^2} = 180$  ways. The total number of admissible numbers, then, is  $120 + 180 = 300$ .

**2.6.36** (a)  $8!/3!3!2! = 560$   
 (b)  $8! = 40,320$   
 (c)  $8!/3!(1!)^5 = 6720$

**2.6.37** (a)  $4! \cdot 3! \cdot 3! = 864$   
 (b)  $3! \cdot 4!3!3! = 5184$  (each of the  $3!$  permutations of the three nationalities can generate  $4!3!3!$  arrangements of the ten people in line)  
 (c)  $10! = 3,628,800$   
 (d)  $10!/4!3!3! = 4200$

**2.6.38** Altogether, the letters in S L U M G U L L I O N can be permuted in  $\frac{11!}{3!2!(1!)^6}$  ways. The seven consonants can be arranged in  $7!/3!(1!)^4$  ways, of which  $4!$  have the property that the three  $L$ 's come first. By the reasoning used in Example 2.6.13, it follows that the number of admissible arrangements is  $4!/(7!/3!) \cdot \frac{11!}{3!2!}$ , or 95,040.

**2.6.39** Imagine a field of 4 entrants ( $A, B, C, D$ ) assigned to positions 1 through 4, where positions 1 and 2 correspond to the opponents for game 1 and positions 3 and 4 correspond to the

- opponents for game 2. Although the four players can be assigned to the four positions in  $4!$  ways, not all of those permutations yield different tournaments. For example,  $\frac{B}{1} \frac{C}{2} \frac{A}{3} \frac{D}{4}$  and  $\frac{A}{1} \frac{D}{2} \frac{B}{3} \frac{C}{4}$  produce the same set of games, as do  $\frac{B}{1} \frac{C}{2} \frac{A}{3} \frac{D}{4}$  and  $\frac{C}{1} \frac{B}{2} \frac{A}{3} \frac{D}{4}$ . In general,  $n$  games can be arranged in  $n!$  ways, and the two players in each game can be permuted in  $2!$  ways. Given a field of  $2n$  entrants, then, the number of distinct pairings is  $(2n)!/n!(2!)^n$ , or  $1 \cdot 3 \cdot 5 \cdots (2n - 1)$ .
- 2.6.40** Since  $x^{12}$  can be the result of the factors  $x^6 \cdot x^6 \cdot 1 \cdots 1$  or  $x^3 \cdot x^3 \cdot x^3 \cdot x^3 \cdot 1 \cdots 1$  or  $x^6 \cdot x^3 \cdot x^3 \cdot 1 \cdots 1$ , the analysis described in Example 2.6.16 implies that the coefficient of  $x^{12}$  is  $\frac{18!}{2!16!} + \frac{18!}{4!14!} + \frac{18!}{1!2!15!} = 5661$ .
- 2.6.41** The letters in E L E E M O S Y N A R Y minus the pair S Y can be permuted in  $10!/3!$  ways. Since S Y can be positioned in front of, within, or behind those ten letters in 11 ways, the number of admissible arrangements is  $11 \cdot 10!/3! = 6,652,800$ .
- 2.6.42** Each admissible spelling of ABRACADABRA can be viewed as a path consisting of 10 steps, five to the right (R) and five to the left (L). Thus, each spelling corresponds to a permutation of the five R's and five L's. There are  $\frac{10!}{5!5!} = 252$  such permutations.
- 2.6.43** Six, because the first four pitches must include two balls and two strikes, which can occur in  $4!/2!2! = 6$  ways.
- 2.6.44**  $9!/2!3!1!3! = 5040$  (recall Example 2.6.16)
- 2.6.45** Think of the six points being numbered 1 through 6. Any permutation of three A's and three B's—for example,  $\frac{A}{1} \frac{A}{2} \frac{B}{3} \frac{B}{4} \frac{A}{5} \frac{B}{6}$ —corresponds to the three vertices chosen for triangle A and the three for triangle B. It follows that  $6!/3!3! = 20$  different sets of two triangles can be drawn.
- 2.6.46** Consider  $k!$  objects categorized into  $(k - 1)!$  groups, each group being of size  $k$ . By Theorem 2.6.2, the number of ways to arrange the  $k!$  objects is  $(k!)/(k!)^{(k-1)!}$ , but the latter must be an integer.
- 2.6.47** There are  $\frac{14!}{2!2!1!2!2!3!1!1!1!}$  total permutations of the letters. There are  $\frac{5!}{2!2!1!} = 30$  arrangements of the vowels, only one of which leaves the vowels in their original position. Thus, there are  $\frac{1}{30} \cdot \frac{14!}{2!2!1!2!1!3!1!1!1!} = 30,270,240$  arrangements of the word leaving the vowels in their original position.
- 2.6.48**  $\frac{15!}{4!3!1!3!1!1!1!1!} = 1,513,512,000$

- 2.6.49** The three courses with A grades can be: emf, emp, emh, efp, efh, eph, mfp, mfh, mph, fph, or 10 possibilities. From the point of view of Theorem 2.6.2, the grade assignments correspond to the set of permutations of three A's and two B's, which equals  $\frac{5!}{3!2!} = 10$ .
- 2.6.50** Since every (unordered) set of two letters describes a different line, the number of possible lines is  $\binom{5}{2} = 10$ .
- 2.6.51** To achieve the two-to-one ratio, six pledges need to be chosen from the set of 10 and three from the set of 15, so the number of admissible classes is  $\binom{10}{6} \cdot \binom{15}{3} = 95,550$ .
- 2.6.52** Of the eight crew members, five need to be on a given side of the boat. Clearly, the remaining three can be assigned to the sides in 3 ways. Moreover, the rowers on each side can be permuted in 4! ways. By the multiplication rule, then, the number of ways to arrange the crew is  $1728 (= 3 \cdot 4! \cdot 4!)$ .
- 2.6.53** (a)  $\binom{9}{4} = 126$   
 (b)  $\binom{5}{2}\binom{4}{2} = 60$   
 (c)  $\binom{9}{4} - \binom{5}{4} - \binom{4}{4} = 120$
- 2.6.54**  $\binom{7}{5} = 21$ ; order does not matter.
- 2.6.55** Consider a simpler problem: Two teams of two each are to be chosen from a set of four players— $A$ ,  $B$ ,  $C$ , and  $D$ . Although a single team can be chosen in  $\binom{4}{2}$  ways, the number of *pairs* of teams is only  $\binom{4}{2}/2$ , because  $[(A\ B), (C\ D)]$  and  $[(C\ D), (A\ B)]$  would correspond to the same matchup. Applying that reasoning here means that the ten players can split up in  $\binom{10}{5}/2 = 126$  ways.
- 2.6.56** Number the spaces between the twenty pages from 1 to 19. Choosing any two of these spaces partitions the reading assignment into three non-zero, numbers,  $x_1$ ,  $x_2$ , and  $x_3$ , corresponding to the numbers of pages read on Monday, Tuesday, and Wednesday,

respectively. Therefore, the number of ways to complete the reading assignment is

$$\binom{19}{2} = 171.$$

- 2.6.57** The four  $I$ 's need to occupy any of the  $\binom{8}{4}$  sets of four spaces between and around the other seven letters. Since the latter can be permuted in  $\frac{7!}{2!4!1!}$  ways, the total number of admissible arrangements is  $\binom{8}{4} \cdot \frac{7!}{2!4!1!} = 7350$ .

$$\begin{aligned} \binom{n+1}{k} - \binom{n}{k-1} &= \frac{(n+1)!}{k!(n+1-k)!} - \frac{n!}{(k-1)!(n-k+1)!} = \frac{(n+1)!}{k!(n+1-k)!} - \frac{n!k}{k!(n-k+1)!} \\ &= \frac{(n+1)! - n!k}{k!(n+1-k)!} = \frac{n!}{k!(n-k)!} \end{aligned}$$

**2.6.59**  $\binom{n}{k+1} / \binom{n}{k} = \frac{n!}{(k+1)!(n-k-1)!} \cdot \frac{k!(n-k)!}{n!} = \frac{n-k}{k+1}$ , so the recursion is

$$\binom{n}{k+1} = \frac{n-k}{k+1} \cdot \binom{n}{k}$$

**2.6.60** Consider the binomial expansion  $(x+1)^n = \sum_{k=0}^n \binom{n}{k} x^k$  as a function of  $x$ . Differentiate twice to obtain  $n(n-1)(x+1)^{n-2} = \sum_{k=2}^n k(k-1) \binom{n}{k} x^{k-2}$ . Setting  $x = 1$  gives

$$n(n-1)2^{n-2} = \sum_{k=2}^n k(k-1) \binom{n}{k}$$

- 2.6.61** The ratio of two successive terms in the sequence is  $\binom{n}{j+1} / \binom{n}{j} = \frac{n-j}{j+1}$ . For small  $j$ ,  $n-j > j+1$ , implying that the terms are increasing. For  $j > \frac{n-1}{2}$ , though, the ratio is less than 1, meaning the terms are decreasing.

- 2.6.62** Four months of daily performance create a need for roughly 120 different sets of jokes. If  $n$  denotes the number of different jokes that Mitch has to learn, the question is asking for the smallest  $n$  for which  $\binom{n}{4} \geq 120$ . By trial and error,  $n = 9$ .

**2.6.63** Using Newton's binomial expansion, the equation  $(1+t)^d \cdot (1+t)^e = (1+t)^{d+e}$  can be written

$$\left( \sum_{j=0}^d \binom{d}{j} t^j \right) \cdot \left( \sum_{j=0}^e \binom{e}{j} t^j \right) = \sum_{j=0}^{d+e} \binom{d+e}{j} t^j$$

Since the exponent  $k$  can arise as  $t^0 \cdot t^k$ ,  $t^1 \cdot t^{k-1}$ ,  $\dots$ , or  $t^k \cdot t^0$ , it follows that

$$\binom{d}{0} \binom{e}{k} + \binom{d}{1} \binom{e}{k-1} + \dots + \binom{d}{k} \binom{e}{0} = \binom{d+e}{k}. \text{ That is, } \binom{d+e}{k} = \sum_{j=0}^k \binom{d}{j} \binom{e}{k-j}.$$

## Section 2.7: Combinatorial Probability

**2.7.1** 
$$\frac{\binom{7}{2} \binom{3}{2}}{\binom{10}{4}}$$

**2.7.2** 
$$P(\text{sum} = 5) = \frac{\text{Number of pairs that sum to 5}}{\text{Total number of pairs}} = \frac{2}{\binom{6}{2}} = \frac{2}{15}.$$

**2.7.3** 
$$P(\text{numbers differ by more than 2}) = 1 - P(\text{numbers differ by one}) - P(\text{numbers differ by 2})$$
  

$$= 1 - 19 / \binom{20}{2} - 18 / \binom{20}{2} = \frac{153}{190} = 0.81.$$

**2.7.4** 
$$P(A \cup B) = P(A) + P(B) - P(A \cap B)$$
  

$$= \frac{\binom{4}{4} \binom{48}{9}}{\binom{52}{13}} + \frac{\binom{4}{4} \binom{48}{9}}{\binom{52}{13}} - \frac{\binom{4}{4} \binom{4}{4} \binom{44}{5}}{\binom{52}{13}}$$

**2.7.5** Let  $A_1$  be the event that an urn with 3W and 3R is sampled; let  $A_2$  be the event that the urn with 5W and 1R is sampled. Let  $B$  be the event that the three chips drawn are white. By Bayes' rule,

$$P(A_2 | B) = \frac{P(B | A_2)P(A_2)}{P(B | A_1)P(A_1) + P(B | A_2)P(A_2)} =$$
  

$$\frac{\left[ \frac{\binom{5}{3} \binom{1}{0}}{\binom{6}{3}} \right] \cdot (1/10)}{\left[ \frac{\binom{3}{3} \binom{3}{0}}{\binom{6}{3}} \right] \cdot (9/10) + \left[ \frac{\binom{5}{3} \binom{1}{0}}{\binom{6}{3}} \right] \cdot (1/10)} = \frac{10}{19}$$

**2.7.6** 
$$\frac{\binom{2}{1}^{50}}{\binom{100}{50}}$$

**2.7.7** 
$$6/6^n = 1/6^{n-1}$$

- 2.7.8** There are 6 faces that could be the “three-of-a-kind” and 5 faces that could be the “two-of-a-kind.” Moreover, the five dice bearing those two numbers could occur in any of  $5!/2!3! = \binom{5}{2}$  orders. It follows that  $P(\text{“full house”}) = 6 \cdot 5 \cdot \binom{5}{2} / 6^5 = 50/6^4$
- 2.7.9** By Theorem, 2.6.2, the  $2n$  grains of sand can be arranged in  $(2n)!/n!n!$  ways. Two of those arrangements have the property that the colors will completely separate. Therefore, the probability of the latter is  $2(n!)^2/(2n)!$
- 2.7.10**  $P(\text{monkey spells CALCULUS}) = 1/[8!/(2!)^3(1!)^2] = 1/5040$ ;  
 $P(\text{monkey spells ALGEBRA}) = 1/[7!/2!(1!)^5] = 2/5040$ .
- 2.7.11**  $P(\text{different floors}) = 7!/7^7$ ;  $P(\text{same floor}) = 7/7^7 = 1/7^6$ . The assumption being made is that all possible departure patterns are equally likely, which is probably not true, since residents living on lower floors would be less inclined to wait for the elevator than would those living on the top floors.
- 2.7.12** The total number of distinguishable permutations of the phrase is  $\frac{23!}{2!2!4!2!1!3!2!4!2!2!1!1!}$ . The number of permutations where all of the S’s are adjacent is counted by treating the S’s as a single letter that appears once. The denominator above will have one of the 4! replaced by 1!. The number of such permutations, then, is  $\frac{23!}{2!2!4!2!1!3!2!1!2!2!1!1!}$ . The probability that the S’s are adjacent is then the ratio of these two terms or  $4!23!/26! = 1/650$ . The requested probability is then the complement,  $649/650$ .
- 2.7.13** The 10 short pieces and 10 long pieces can be lined up in a row in  $20!/(10)!(10)!$  ways. Consider each of the 10 pairs of consecutive pieces as defining the reconstructed sticks. Each of those pairs could combine a short piece (S) and a long piece (L) in two ways: SL or LS. Therefore, the number of permutations that would produce 10 sticks, each having a short and a long component is  $2^{10}$ , so the desired probability is  $2^{10} / \binom{20}{10}$ .
- 2.7.14**  $6!/6^6$
- 2.7.15** Any of  $\binom{k}{2}$  people could share any of 365 possible birthdays. The remaining  $k - 2$  people can generate  $364 \cdot 363 \cdots (365 - k + 2)$  sequences of distinct birthdays. Therefore,  
 $P(\text{exactly one match}) = \binom{k}{2} \cdot 365 \cdot 364 \cdots (365 - k + 2) / 365^k$ .
- 2.7.16** The expression  $\binom{12}{1} \binom{11}{1} \binom{10}{1}$  orders the denominations of the three single cards—in effect, each set of three denominations would be counted 3! times. The denominator ( $= \binom{52}{5}$ ) in that particular probability calculation, though, does not consider the cards to be ordered. To

be consistent, the denominations for the three single cards must be treated as a combination, meaning the number of choices is  $\binom{12}{3}$ .

**2.7.17** To get a flush, Dana needs to draw any three of the remaining eleven diamonds. Since only forty-seven cards are effectively left in the deck (others may already have been dealt, but their identities are unknown),  $P(\text{Dana draws to flush}) = \binom{11}{3} / \binom{47}{3}$ .

**2.7.18**  $P(\text{draws to full house or four-of-a-kind})$   
 $= P(\text{draws to full house}) + P(\text{draws to four-of-a-kind}) = \frac{3}{47} + \frac{1}{47} = \frac{4}{47}$ .

**2.7.19** There are two pairs of cards that would give Tim a straight flush (5 of clubs and 7 of clubs or 7 of clubs and 10 of clubs). Therefore,  $P(\text{Tim draws to straight flush}) = 2 / \binom{47}{2}$ . A flush, by definition, consists of five cards in the same suit whose denominations are not all consecutive. It follows that  $P(\text{Tim draws to flush}) = \left[ \binom{10}{2} - 2 \right] / \binom{47}{2}$ , where the “2” refers to the straight flushes cited earlier.

**2.7.20** A sum of 48 requires four 10’s and an 8 or three 10’s and two 9’s; a sum of 49 requires four 10’s and a 9; no sums higher than 49 are possible. Therefore,  
 $P(\text{sum} \geq 48) = \left[ \binom{4}{4} \binom{4}{1} + \binom{4}{3} \binom{4}{2} + \binom{4}{4} \binom{4}{1} \right] / \binom{52}{5} = 32 / \binom{52}{5}$ .

**2.7.21**  $\binom{5}{3} \binom{4}{2}^3 \binom{3}{1} \binom{4}{2} \binom{2}{1} \binom{4}{1} / \binom{52}{9}$

**2.7.22**  $\binom{32}{13} / \binom{52}{13}$

**2.7.23**  $\left[ \binom{2}{1} \binom{2}{1} \right]^4 \binom{32}{4} / \binom{48}{12}$

## Chapter 3: Random Variables

### Section 3.2: Binomial and Hypergeometric Probabilities

**3.2.1** The number of days,  $k$ , the stock rises is binomial with  $n = 4$  and  $p = 0.25$ . The stock will be the same after four days if  $k = 2$ . The probability that  $k = 2$  is  $\binom{4}{2}(0.25)^2(0.75)^2 = 0.211$

**3.2.2** Let  $k$  be the number of control rods properly inserted. The system fails if  $k \leq 4$ . The probability of that occurrence is given by the binomial probability sum

$$\sum_{k=0}^4 \binom{10}{k} (0.8)^k (0.2)^{10-k} = 0.0064$$

**3.2.3** The probability of 12 female presidents is  $0.23^{12}$ , which is approximately  $1/50,000,000$ .

**3.2.4** 
$$1 - \binom{6}{0}(0.153)^0(0.847)^6 - \binom{6}{1}(0.153)^1(0.847)^5 = 0.231$$

**3.2.5** 
$$1 - \sum_{k=8}^{11} \binom{11}{k} (0.9)^k (0.1)^{11-k} = 0.0185$$

**3.2.6** The probability of  $k$  sightings is given by the binomial probability model with  $n = 10,000$  and  $p = 1/100,000$ . The probability of at least one genuine sighting is the probability that  $k \geq 1$ . The probability of the complementary event,  $k = 0$ , is  $(99,999 / 100,000)^{10,000} = 0.905$ . Thus, the probability that  $k \geq 1$  is  $1 - 0.905 = 0.095$ .

**3.2.7** For the two-engine plane,  $P(\text{Flight lands safely}) = P(\text{One or two engines work properly})$   
$$= \binom{2}{1}(0.6)^1(0.4)^1 + \binom{2}{2}(0.6)^2(0.4)^0 = 0.84$$

For the four-engine plane,  $P(\text{Flight lands safely}) = P(\text{Two or more engines work properly})$

$$= \binom{4}{2}(0.6)^2(0.4)^2 + \binom{4}{3}(0.6)^3(0.4)^1 + \binom{4}{4}(0.6)^4(0.4)^0 = 0.8208$$

The two-engine plane is a better choice.

**3.2.8** Probabilities for the first system are binomial with  $n = 50$  and  $p = 0.05$ . The probability that  $k \geq 1$  is  $1 - (0.95)^{50} = 1 - 0.077 = 0.923$ .

Probabilities for the second system are binomial with  $n = 100$  and  $p = 0.02$ . The probability that  $k \geq 1$  is  $1 - (0.98)^{100} = 1 - 0.133 = 0.867$

System 2 is superior from a bulb replacement perspective.

**3.2.9** The number of 6's obtained in  $n$  tosses is binomial with  $p = 1/6$ . The first probability in question has  $n = 6$ . The probability that  $k \geq 1$  is  $1 - (5/6)^6 = 1 - 0.33 = 0.67$ . For the second situation,  $n = 12$ . The probability that  $k \geq 2$  one minus the probability that  $k = 0$  or 1, which is  $1 - (5/6)^{12} - 12(1/6)(5/6)^{11} = 0.62$ . Finally, take  $n = 18$ . The probability that  $k \geq 3$  is one minus the probability that  $k = 0, 1$ , or 2, which is  $1 - (5/6)^{18} - 18(1/6)(5/6)^{17} - 153(1/6)^2(5/6)^{16} = 0.60$ .

**3.2.10** The number of missile hits on the plane is binomial with  $n = 6$  and  $p = 0.2$ . The probability that the plane will crash is the probability that  $k \geq 2$ . This event is the complement of the event that  $k = 0$  or 1, so the probability is  $1 - (0.8)^6 - 6(0.2)(0.8)^5 = 0.345$

The number of rocket hits on the plane is also binomial, but with  $n = 10$  and  $p = 0.05$ .

The probability that the boat will be disabled is  $P(k \geq 1)$ , which is  $1 - (0.95)^{10} = 0.401$

**3.2.11** The number of girls is binomial with  $n = 4$  and  $p = 1/2$ . The probability of two girls and two boys is  $\binom{4}{2}(0.5)^4 = 0.375$ . The probability of three and one is  $2\binom{4}{3}(0.5)^4 = 0.5$ , so the latter is more likely.

- 3.2.12** The number of recoveries if the drug is effective is binomial with  $n = 12$  and  $p = 1/2$ . The drug will be discredited if the number of recoveries is 6 or less. The probability of this is

$$\sum_{k=0}^6 \binom{12}{k} (0.5)^{12} = 0.613.$$

- 3.2.13** The probability it takes  $k$  calls to get four drivers is  $\binom{k-1}{3} 0.80^4 0.20^{k-4}$ . We seek the smallest number  $n$  so that  $\sum_{k=4}^n \binom{k-1}{3} 0.80^4 0.20^{k-4} \geq 0.95$ . By trial and error,  $n = 7$ .

- 3.2.14** The probability of any shell hitting the bunker is  $30/500 = 0.06$ . The probability of exactly  $k$  shells hitting the bunker is  $p(k) = \binom{25}{k} (0.06)^k (0.94)^{25-k}$ . The probability the bunker is destroyed is  $1 - p(0) - p(1) - p(2) = 0.187$ .

- 3.2.15** (1) The probability that any one of the seven measurements will be in the interval  $(1/2, 1)$  is 0.50. The probability that exactly three will fall in the interval is  $\binom{7}{3} 0.5^7 = 0.273$
- (2) The probability that any one of the seven measurements will be in the interval  $(3/4, 1)$  is 0.25. The probability that fewer than 3 will fall in the interval is

$$\sum_{k=0}^2 \binom{7}{k} (0.25)^k (0.75)^{7-k} = 0.756$$

- 3.2.16** Use the methods of Example 3.2.3 for  $p = 0.5$ . Then the probabilities of Team A winning the series in 4, 5, 6, and 7 games are 0.0625, 0.125, 0.156, and 0.156, respectively. Since Team B has the same set of probabilities, the probability of the series ending in 4, 5, 6, and 7 games is double that for A, or 0.125, 0.250, 0.312, and 0.312, respectively. The “expected” frequencies are the number of years, 64, times the probability of each length. For example, we would “expect”  $64(0.125) = 8.0$  series of 4 games. The table below gives the comparison of observed and expected frequencies.

	Observed	Expected
Number of games	Number of years	Number of years
4	13	$64(0.125) = 8.0$
5	11	$64(0.250) = 16.0$
6	14	$64(0.312) = 20.0$
7	26	$64(0.312) = 20.0$

Note that the model has equal expected frequencies for 6 and 7 length series, but the observed numbers are quite different. This model does not fit the data well.

**3.2.17** The probability of more than five successes is  $\sum_{k=6}^{12} \binom{12}{k} (0.3)^k (0.7)^{12-k} = 0.118$ .

In a month, there are roughly two hundred forty college-days, so a prediction of the number of days some college has to wait is approximately 28. This suggests that at least one more technician may be needed.

**3.2.18** Any particular sequence having  $k_1$  of Outcome 1 and  $k_2$  of Outcome 2, must have  $n - k_1 - k_2$  of Outcome 3. The probability of such a sequence is  $p_1^{k_1} p_2^{k_2} (1 - p_1 - p_2)^{n-k_1-k_2}$ .

The number of such sequences depends on the number of ways to choose the  $k_1$  positions in the sequence for Outcome 1 and the  $k_2$  positions for Outcome 2. The  $k_1$  positions can be chosen in  $\binom{n}{k_1}$  ways. For each such choice, the  $k_2$  positions can be chosen in  $\binom{n-k_1}{k_2}$  ways. Thus,

$$\begin{aligned}
 P(k_1 \text{ of Outcome 1 and } k_2 \text{ of Outcome 2}) &= \binom{n}{k_1} \binom{n-k_1}{k_2} p_1^{k_1} p_2^{k_2} (1 - p_1 - p_2)^{n-k_1-k_2} \\
 &= \frac{n!}{k_1! (n-k_1)!} \frac{(n-k_1)!}{k_2! (n-k_1-k_2)!} p_1^{k_1} p_2^{k_2} (1 - p_1 - p_2)^{n-k_1-k_2} \\
 &= \frac{n!}{k_1! k_2! (n-k_1-k_2)!} p_1^{k_1} p_2^{k_2} (1 - p_1 - p_2)^{n-k_1-k_2}
 \end{aligned}$$

**3.2.19** In the notation of Question 3.2.18,  $p_1 = 0.5$  and  $p_2 = 0.3$ , with  $n = 10$ . Then the probability of 3 of Outcome 1 and 5 of Outcome 2 is  $\frac{10!}{3!5!2!}(0.5)^3(0.3)^5(0.2)^2 = 0.031$

**3.2.20** Use the hypergeometric model with  $N = 12$ ,  $n = 5$ ,  $r = 4$ , and  $w = 12 - 4 = 8$ . The probability that

the committee will contain two accountants ( $k = 2$ ) is  $\frac{\binom{4}{2}\binom{8}{3}}{\binom{12}{5}} = 14/33$

**3.2.21** “At least twice as many black bears as tan-colored” translates into spotting 4, 5, or 6 black

bears. The probability is  $\frac{\binom{6}{4}\binom{3}{2}}{\binom{9}{6}} + \frac{\binom{6}{5}\binom{3}{1}}{\binom{9}{6}} + \frac{\binom{6}{6}\binom{3}{0}}{\binom{9}{6}} = 64/84$

**3.2.22** The probabilities are hypergeometric with  $N = 4050$ ,  $n = 65$ ,  $r = 514$ , and  $w = 4050 - 514 = 3536$ . The probability that  $k$  children have not been vaccinated is

$$\frac{\binom{514}{k}\binom{3536}{65-k}}{\binom{4050}{65}}, k = 0, 1, 2, \dots, 65$$

**3.2.23** The probability that  $k$  nuclear missiles will be destroyed by the anti-ballistic missiles is hypergeometric with  $N = 10$ ,  $n = 7$ ,  $r = 6$ , and  $w = 10 - 6 = 4$ . The probability the Country B will be hit by at least one nuclear missile is one minus the probability that  $k = 6$ , or

$$1 - \frac{\binom{6}{6}\binom{4}{1}}{\binom{10}{7}} = 0.967$$

**3.2.24** Let  $k$  be the number of questions chosen that Anne has studied. Then the probabilities for  $k$  are hypergeometric with  $N = 10$ ,  $n = 5$ ,  $r = 8$ , and  $w = 10 - 8 = 2$ . The probability of her getting at least four correct is the probability that  $k = 4$  or 5, which is

$$\frac{\binom{8}{4}\binom{2}{1}}{\binom{10}{5}} + \frac{\binom{8}{5}\binom{2}{0}}{\binom{10}{5}} = \frac{140}{252} + \frac{56}{252} = 0.778$$

**3.2.25** The probabilities for the number of men chosen are hypergeometric with  $N = 18$ ,  $n = 5$ ,  $r = 8$ , and  $w = 10$ . The event that both men and women are represented is the complement of the event

$$\text{that 0 or 5 men will be chosen, or } 1 - \frac{\binom{8}{0}\binom{10}{5}}{\binom{18}{5}} + \frac{\binom{8}{5}\binom{10}{0}}{\binom{18}{5}} = 1 - \frac{252}{8568} + \frac{56}{8568} = 0.964$$

**3.2.26** The probability is hypergeometric with  $N = 80$ ,  $n = 10$ ,  $r = 20$ , and  $w = 60$ , and equals

$$\frac{\binom{20}{6}\binom{60}{4}}{\binom{80}{10}} = 0.0115$$

**3.2.27** First, calculate the probability that exactly one real diamond is taken during the first three grabs. There are three possible positions in the sequence for the real diamond, so this

$$\text{probability is } \frac{3(10)(25)(24)}{(35)(34)(33)}.$$

The probability of a real diamond being taken on the fourth removal is  $9/32$ .

$$\text{Thus, the desired probability is } \frac{3(10)(25)(24)}{(35)(34)(33)} \times \frac{9}{32} = \frac{162,000}{1,256,640} = 0.129.$$

**3.2.28** First, suppose that the  $k$  red balls are drawn first. The probability of this is

$$\frac{r}{N} \cdot \frac{r-1}{N-1} \cdots \frac{r-(k-1)}{N-k+1} \cdot \frac{w}{N-k} \cdot \frac{w-1}{N-k-1} \cdots \frac{w-(n-k)+1}{N-n+1} = \frac{\frac{r}{(r-k)!} \cdot \frac{w!}{[w-(n-k)]!}}{\frac{N!}{(N-n)!}}$$

But this is also the probability of any sequence of draws, which are determined by the position of the red balls. Thus, there are  $\binom{n}{k}$  such, so the probability in this model of  $k$  red balls is

$$\binom{n}{k} \cdot \frac{\frac{r}{(r-k)!} \cdot \frac{w!}{[w-(n-k)]!}}{\frac{N!}{(N-n)!}} = \frac{\frac{r}{k!(r-k)!} \cdot \frac{w!}{(n-k)![w-(n-k)]!}}{\frac{N!}{n!(N-n)!}} = \frac{\binom{r}{k} \binom{w}{n-k}}{\binom{N}{n}}$$

which is hypergeometric.

**3.2.29** The  $k$ -th term of  $(1 + \mu)^N = \binom{N}{k} \mu^k$

$$(1 + \mu)^r (1 + \mu)^{N-r} = \left( \sum_{i=1}^r \binom{r}{i} \mu^i \right) \left( \sum_{j=1}^{N-r} \binom{N-r}{j} \mu^j \right)$$

The  $k$ -th term of this product is  $\sum_{i=1}^r \binom{r}{i} \binom{N-r}{k-i} \mu^k$

Equating coefficients gives  $\binom{N}{k} = \sum_{i=1}^k \binom{r}{i} \binom{N-r}{k-i}$ .

Dividing through by  $\binom{N}{k}$  shows that the hypergeometric terms sum to 1.

**3.2.30**

$$\frac{\binom{r}{k+1} \binom{w}{n-k-1}}{\binom{N}{n}} \div \frac{\binom{r}{k} \binom{w}{n-k}}{\binom{N}{n}} = \binom{r}{k+1} \binom{w}{n-k-1} \div \binom{r}{k} \binom{w}{n-k}$$

$$= \binom{r}{k+1} \binom{w}{n-k-1} \div \binom{r}{k} \binom{w}{n-k}$$

$$\begin{aligned}
&= \frac{r!}{(k+1)!(r-k-1)!} \cdot \frac{w!}{(n-k-1)!(w-n+k+1)!} \cdot \frac{k!(r-k)!}{r!} \cdot \frac{(n-k)!(w-n+k)!}{w!} \\
&= \frac{n-k}{(k+1)} \cdot \frac{r-k}{(w-n+k+1)}.
\end{aligned}$$

**3.2.31** Let  $W_0$ ,  $W_1$  and  $W_2$  be the events of drawing zero, one, or two white chips, respectively, from Urn I. Let  $A$  be the event of drawing a white chip from Urn II.

Then  $P(A) = P(A|W_0)P(W_0) + P(A|W_1)P(W_1) + P(A|W_2)P(W_2)$

$$= \frac{5}{11} \frac{\binom{5}{2} \binom{4}{0}}{\binom{9}{2}} + \frac{6}{11} \frac{\binom{5}{1} \binom{4}{1}}{\binom{9}{2}} + \frac{7}{11} \frac{\binom{5}{0} \binom{4}{2}}{\binom{9}{2}} = 53/99$$

**3.2.32** For any value of  $r$  = number of defective items, the probability of accepting the sample is

$$p_r = \frac{\binom{r}{0} \binom{100-r}{10}}{\binom{100}{10}} + \frac{\binom{r}{1} \binom{100-r}{9}}{\binom{100}{10}}$$

Then the operating characteristic curve is the plot of the presumed percent defective versus the probability of accepting the shipment, or  $100(r/100) = r$  on the  $x$ -axis and  $p_r$  on the  $y$ -axis. If there are 16 defective, you will accept the shipment approximately 50% of the time.

**3.2.33** There are  $\frac{r!}{r_1!r_2!r_3!}$  ways to divide the red balls into three groups of the given sizes. There are  $\frac{(N-r)!}{(n_1-r_1)!(n_2-r_2)!(n_3-r_3)!}$  ways to divide the white balls into the three groups of the required sizes. The total number of ways to divide the  $N$  objects into groups of  $n_1$ ,  $n_2$ , and  $n_3$  objects is  $\frac{N!}{n_1!n_2!n_3!}$ . Thus, the desired probability is

$$\frac{\frac{r!}{r_1!r_2!r_3!} \frac{(N-r)!}{(n_1-r_1)!(n_2-r_2)!(n_3-r_3)!}}{\frac{N!}{n_1!n_2!n_3!}} = \frac{\binom{n_1}{r_1} \binom{n_2}{r_2} \binom{n_3}{r_3}}{\binom{N}{r}}.$$

**3.2.34** First, calculate the probability that the first group contains two disease carriers and the others

have one each. The probability of this, according to Question 3.2.33, is  $\frac{\binom{7}{2} \binom{7}{1} \binom{7}{1}}{\binom{21}{4}} = 49/285$ .

The probability that either of the other two groups has 2 carriers and the others have one is the same. Thus, the probability that each group has at least one diseased member is  $3 \frac{49}{285} = \frac{49}{95} = 0.516$ . Then the probability that at least one group is disease free is  $1 - 0.516 = 0.484$ .

**3.2.35** There are  $\binom{N}{n}$  total ways to choose the sample. There are  $\binom{n_i}{k_i}$  ways to arrange for  $k_i$  of the  $n_i$  objects to be chosen, for each  $i$ . Using the multiplication rule shows that the probability of getting  $k_1$  objects of the first kind,  $k_2$  objects of the second kind, ...,  $k_t$  objects of the  $t$ -th kind

$$\text{is } \frac{\binom{n_1}{k_1} \binom{n_2}{k_2} \cdots \binom{n_t}{k_t}}{\binom{N}{n}}$$

**3.2.36** In the notation of Question 3.2.33, let  $n_1 = 5$ ,  $n_2 = 4$ ,  $n_3 = 4$ ,  $n_4 = 3$ , so  $N = 16$ . The sample size is given to be  $n = 8$ , and  $k_1 = k_2 = k_3 = k_4 = 2$ . Then the probability that each class has two

representatives is 
$$\frac{\binom{5}{2}\binom{4}{2}\binom{4}{2}\binom{3}{2}}{\binom{16}{8}} = \frac{(10)(6)(6)(3)}{12,870} = \frac{1080}{12,870} = 0.084.$$

## Section 3.3: Discrete Random Variables

**3.3.1** (a) Each outcome has probability  $1/10$

Outcome	$X = \text{larger no. drawn}$
1, 2	2
1, 3	3
1, 4	4
1, 5	5
2, 3	3
2, 4	4
2, 5	5
3, 4	4
3, 5	5
4, 5	5

Counting the number of each value of the larger of the two and multiplying by  $1/10$  gives the pdf:

$k$	$p_X(k)$
2	$1/10$
3	$2/10$
4	$3/10$
5	$4/10$

(b)

Outcome	$X$ = larger no. drawn	$V$ = sum of two nos.
1, 2	2	3
1, 3	3	4
1, 4	4	5
1, 5	5	6
2, 3	3	5
2, 4	4	6
2, 5	5	7
3, 4	4	7
3, 5	5	8
4, 5	5	9

k	$p_X(k)$
3	1/10
4	1/10
5	2/10
6	2/10
7	2/10
8	1/10
9	1/10

- 3.3.2** (a) There are  $5 \times 5 = 25$  total outcomes. The set of outcomes leading to a maximum of  $k$  is  $(X = k) = \{(j, k) | 1 \leq j \leq k - 1\} \cup \{(k, j) | 1 \leq j \leq k - 1\} \cup \{(k, k)\}$ , which has  $2(k - 1) + 1 = 2k - 1$  elements. Thus,  $p_X(k) = (2k - 1)/25$

(b)

Outcomes	$V = \text{sum of two nos.}$
(1, 1)	2
(1, 2) (2, 1)	3
(1, 3) (2, 2) (3, 1)	4
(1, 4) (2, 3) (3, 2) (4, 1)	5
(1, 5) (2, 4) (3, 3) (4, 2) (5, 1)	6
(2, 5) (3, 4) (4, 3) (5, 2)	7
(3, 5) (4, 4) (5, 3)	8
(4, 5) (5, 4)	9
(5, 5)	10

$$p_V(k) = (k - 1)/25 \text{ for } k = 1, 2, 3, 4, 5, 6 \text{ and } p_V(k) = (11 - k)/25$$

**3.3.3**  $p_X(k) = P(X = k) = P(X \leq k) - P(X \leq k - 1)$ . But the event  $(X \leq k)$  occurs when all three dice are  $\leq k$  and that can occur in  $k^3$  ways. Thus  $P(X = k) = k^3/216$ .

Similarly,  $P(X \leq k - 1) = (k - 1)^3/216$ . Thus  $p_X(k) = k^3/216 - (k - 1)^3/216$ .

**3.3.4**  $p_X(1) = 6/6^3 = 6/216 = 1/36$

$$p_X(2) = 3(6)(5)/6^3 = 90/216 = 15/36$$

$$p_X(3) = (6)(5)(4)/6^3 = 120/216 = 20/36$$

**3.3.5**

Outcomes	$V = \text{no. heads} - \text{no. tails}$
(H, H, H)	3
(H, H, T) (H, T, H) (T, H, H)	1
(T, T, H) (T, H, T) (T, H, H)	-1
(T, T, T)	-3

$$p_X(3) = 1/8, p_X(1) = 3/8, p_X(-1) = 3/8, p_X(-3) = 1/8$$

## 3.3.6

Outcomes	$k$	$p_X(k)$
(1, 1)	2	$(1/6)(1/6) = 1/36$
(2, 1)	3	$(2/6)(1/6) = 2/36$
(1, 3) (3, 1)	4	$(1/6)(1/6) + (2/6)(1/6) = 3/36$
(1, 4) (2, 3) (4, 1)	5	$(1/6)(1/6) + (2/6)(1/6) + (1/6)(1/6) = 4/36$
(1, 5) (2, 4) (3, 3)	6	$(1/6)(1/6) + (2/6)(1/6) + (2/6)(1/6) = 5/36$
(1, 6) (2, 5) (3, 4) (4, 3)	7	$(1/6)(1/6) + (2/6)(1/6) + (2/6)(1/6) + (1/6)(1/6) = 6/36$
(2, 6) (3, 5) (4, 4)	8	$(2/6)(1/6) + (2/6)(1/6) + (1/6)(1/6) = 5/36$
(1, 8) (3, 6) (4, 5)	9	$(1/6)(1/6) + (2/6)(1/6) + (1/6)(1/6) = 4/36$
(2, 8) (4, 6)	10	$(2/6)(1/6) + (1/6)(1/6) = 3/36$
(3, 8)	11	$(2/6)(1/6) = 2/36$
(4, 8)	12	$(1/6)(1/6) = 1/36$

**3.3.7** This is similar to Question 3.3.5. If there are  $k$  steps to the right (heads), then there are  $4 - k$  steps to the left (tails). The final position  $X$  is number of heads – number of tails  
 $= k - (4 - k) = 2k - 4$ . The probability of this is the binomial of getting  $k$  heads in 4 tosses =  
 $\binom{4}{k} \frac{1}{16}$ . Thus,  $p_X(2k - 4) = \binom{4}{k} \frac{1}{16}$ ,  $k = 0, 1, 2, 3, 4$

**3.3.8** 
$$p_X(2k - 4) = \binom{4}{k} \left(\frac{2}{3}\right)^k \left(\frac{1}{3}\right)^{4-k}, k = 0, 1, 2, 3, 4$$

**3.3.9** Consider the case  $k = 0$  as an example. If you are on the left, with your friend on your immediate right, you two can stand in positions 1, 2, 3, or 4. The remaining people can stand in  $3!$  ways. Each of these must be multiplied by 2, since your friend could be the one on the left. The total number of permutations of the five people is  $5!$  Thus,  $p_X(0) = (2)(4)(3!)/5! = 48/120 = 4/10$ . In a similar manner  
 $p_X(1) = (2)(3)(3!)/5! = 36/120 = 3/10$   
 $p_X(2) = (2)(2)(3!)/5! = 24/120 = 2/10$   
 $p_X(3) = (2)(1)(3!)/5! = 12/120 = 1/10$

$$3.3.10 \quad p_{X_1}(k) = p_{X_2}(k) = \frac{\binom{2}{k} \binom{2}{2-k}}{\binom{4}{2}}, \quad k = 0, 1, 2. \quad \text{For } X_1 + X_2 = m, \text{ let } X_1 = k \text{ and } X_2 = m - k, \text{ for}$$

$k = 0, 1, \dots, m$ . Then  $p_{X_3}(m) = \sum_{k=0}^m p_{X_1}(k) p_{X_2}(m-k)$ ,  $m = 0, 1, 2, 3, 4$ , or

$m$	$p_{X_3}(m)$
0	1/36
1	2/9
2	1/2
3	2/9
4	1/36

$$3.3.11 \quad \text{By Theorem 3.8.1, } p_{2X+1}(k) = p_X\left(\frac{k-1}{2}\right) = \left(\frac{4}{k-1}\right) \left(\frac{2}{3}\right)^{\frac{k-1}{2}} \left(\frac{1}{3}\right)^{4-\frac{k-1}{2}}, \quad k = 1, 3, 5, 7, 9$$

$$3.3.12 \quad F_X(k) = P(X \leq k) = k^3, \text{ as explained in the solution to Question 3.3.3.}$$

$$3.3.13 \quad F_X(k) = P(X \leq k) = \sum_{j=0}^k P(X = j) = \sum_{j=0}^k \binom{4}{j} \left(\frac{1}{6}\right)^j \left(\frac{5}{6}\right)^{4-j}$$

$$3.3.14 \quad p_X(k) = F_X(k) - F_X(k-1) = \frac{k(k+1)}{42} - \frac{(k-1)k}{42} = \frac{k}{21}$$

$$3.3.15 \quad f_X(k) = F_X(k) - F_X(k-1) = [1 - (1-p)^k] - [1 - (1-p)^{k-1}] = p(1-p)^{k-1},$$

$k = 1, 2, \dots$  (Geometric)

$$3.3.16 \quad (a) \quad F_X(k) = \frac{\binom{k}{5}}{\binom{36}{5}}, \text{ so } p_X(k) = \frac{\binom{k-1}{4}}{\binom{36}{5}}$$

$$(b) \quad p_X(36) = \frac{\binom{36-1}{4}}{\binom{36}{5}} - \frac{\binom{35-1}{4}}{\binom{36}{5}} = \frac{5}{36} - \frac{5}{36 \cdot 35} \text{ or approximately } 0.135$$

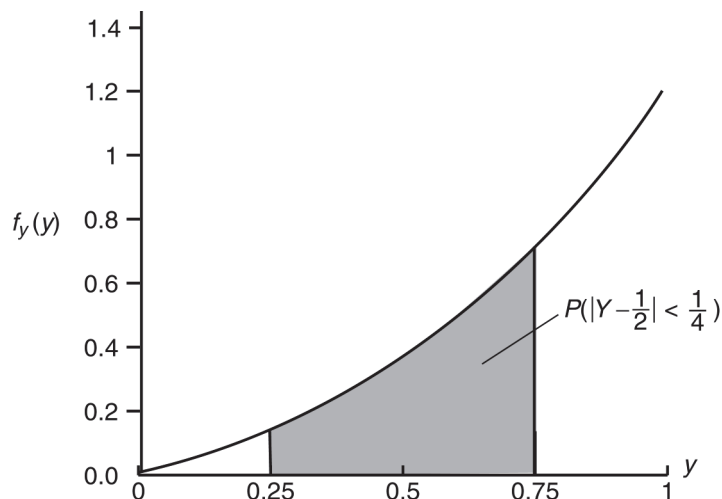

(c) In 108 plays, the expected number of times 36 appears is  $108(0.135) = 14.2$ , very close to the observed number of 15.

## Section 3.4: Continuous Random Variables

$$3.4.1 \quad P(0 \leq Y \leq 1/2) = \int_0^{1/2} 4y^3 dy = y^4 \Big|_0^{1/2} = 1/16$$

$$3.4.2 \quad P(3/4 \leq Y \leq 1) = \int_{3/4}^1 \left( \frac{2}{3} + \frac{2}{3}y \right) dy = \frac{2y}{3} + \frac{y^2}{3} \Big|_{3/4}^1 = 1 - \frac{11}{16} = \frac{5}{16}$$

$$3.4.3 \quad P(|Y - 1/2| < 1/4) = P(1/4 < Y < 3/4) = \int_{1/4}^{3/4} \frac{3}{2}y^2 dy = \frac{y^3}{2} \Big|_{1/4}^{3/4} = \frac{27}{128} - \frac{1}{128} = \frac{26}{128} = \frac{13}{64}$$

$$3.4.4 \quad P(Y > 1) = \int_1^3 (1/9)y^2 dy = (1/27)y^3 \Big|_1^3 = 1 - 1/27 = 26/27$$

**3.4.5** Let  $Y$  be the time of an accident. Given is  $P(Y \leq 40) = 1 - e^{-40\lambda} = 0.25$ . Then  $\lambda = 0.007$ .  
 $P(Y \leq 75) = 1 - e^{-(75)(0.007)} = 0.408$ .

**3.4.6** Clearly the function given is non-negative. We must show that it integrates to 1.

$$\begin{aligned} \int_0^1 (n+2)(n+1)y^n(1-y)dy &= \int_0^1 (n+2)(n+1)(y^n - y^{n+1})dy = (n+2)(n+1) \left( \frac{y^{n+1}}{n+1} - \frac{y^{n+2}}{n+2} \right) \Bigg|_0^1 \\ &= \left[ (n+2)y^{n+1} - (n+1)y^{n+2} \right]_0^1 = 1 \end{aligned}$$

**3.4.7**  $F_Y(y) = P(Y \leq y) = \int_0^y 4t^3 dt = t^4 \Big|_0^y = y^4$ . Then  $P(Y \leq 1/2) = F_Y(1/2) = (1/2)^4 = 1/16$

**3.4.8**  $F_Y(y) = P(Y \leq y) = \int_0^y \lambda e^{-\lambda t} dt = -e^{-\lambda t} \Big|_0^y = 1 - e^{-\lambda y}$

**3.4.9** For  $y < -1$ ,  $F_Y(y) = 0$

$$\text{For } -1 \leq y < 0, F_Y(y) = \int_{-1}^y (1+t)dt = \frac{1}{2} + y + \frac{1}{2}y^2$$

$$\text{For } 0 \leq y \leq 1, F_Y(y) = \int_{-1}^y (1-|t|)dt = \frac{1}{2} + \int_0^y (1-t)dt = \frac{1}{2} + y - \frac{1}{2}y^2$$

For  $y > 1$ ,  $F_Y(y) = 1$

**3.4.10** (1)  $P(1/2 < Y \leq 3/4) = F_Y(3/4) - F_Y(1/2) = (3/4)^2 - (1/2)^2 = 0.3125$

(2)  $f_Y(y) = \frac{d}{dy} F_Y = \frac{d}{dy} y^2 = 2y, 0 \leq y < 1$

$$P(1/2 < Y \leq 3/4) = \int_{1/2}^{3/4} 2y dy = y^2 \Big|_{1/2}^{3/4} = 0.3125$$

**3.4.11** (a)  $P(Y < 2) = F_Y(2)$ , since  $F_Y$  is continuous over  $[0, 2]$ . Then  $F_Y(2) = \ln 2 = 0.693$

(b)  $P(2 < Y \leq 2.5) = F_Y(2.5) - F_Y(2) = \ln 2.5 - \ln 2 = 0.223$

(c) The probability is the same as (b) since  $F_Y$  is continuous over  $[0, e]$

(d)  $f_Y(y) = \frac{d}{dy} F_Y(y) = \frac{d}{dy} \ln y = \frac{1}{y}, 1 \leq y \leq e$

**3.4.12** First note that  $f_Y(y) = \frac{d}{dy} F_Y(y) = \frac{d}{dy} (4y^3 - 3y^4) = 12y^2 - 12y^3, 0 \leq y \leq 1$ .

Then  $P(1/4 < Y \leq 3/4) = \int_{1/4}^{3/4} (12y^2 - 12y^3) dy = (4y^3 - 3y^4) \Big|_{1/4}^{3/4} = 0.6875$ .

**3.4.13**  $f_Y(y) = \frac{d}{dy} \frac{1}{12} (y^2 + y^3) = \frac{1}{6} y + \frac{1}{4} y^2, 0 \leq y \leq 2$

**3.4.14** Integrating by parts, we find that  $F_Y(y) = \int_0^y t e^{-t} dt = -t e^{-t} - e^{-t} \Big|_0^y = 1 - (1 + y) e^{-y}$ .

Using Newton's method, or by computer trial and error, which is easier, we find that

$F_Y(1.678) = 0.50$ .

**3.4.15**  $F'(y) = -1(1 + e^{-y})^{-2}(-e^{-y}) = \frac{e^{-y}}{(1 + e^{-y})^2} > 0$ , so  $F(y)$  is increasing. The other two assertions

follow from the facts that  $\lim_{y \rightarrow -\infty} e^{-y} = \infty$  and  $\lim_{y \rightarrow \infty} e^{-y} = 0$ .

$$3.4.16 \quad F_W(w) = P(W \leq w) = P(2Y + 1 \leq w) = P(Y \leq \frac{w-1}{2}) = F_Y(\frac{w-1}{2})$$

Differentiate both ends of the above to obtain  $f_W(w) = \frac{1}{2} f_Y(\frac{w-1}{2}) = \frac{1}{2} \cdot 4 \left( \frac{w-1}{2} \right)^3 = \frac{1}{4} (w-1)^3$ .

Also,  $0 \leq y \leq 1$  implies  $1 \leq 2y + 1 \leq 3$ , so  $1 \leq w \leq 3$

$$3.4.17 \quad P(-a < Y < a) = P(-a < Y \leq 0) + P(0 < Y < a)$$

$$= \int_{-a}^0 f_Y(y) dy + \int_0^a f_Y(y) dy = -\int_a^0 f_Y(-y) dy + \int_0^a f_Y(y) dy$$

$$= \int_0^a f_Y(y) dy + \int_0^a f_Y(y) dy = 2[F_Y(a) - F_Y(0)]$$

But by the symmetry of  $f_Y$ ,  $F_Y(0) = 1/2$ . Thus,  $2[F_Y(a) - F_Y(0)] = 2[F_Y(a) - 1/2] = 2F_Y(a) - 1$

$$3.4.18 \quad F_Y(y) = \int_0^y (1/\lambda) e^{-t/\lambda} dt = 1 - e^{-y/\lambda}, \text{ so } h(y) = \frac{(1/\lambda) e^{-y/\lambda}}{1 - (1 - e^{-y/\lambda})} = 1/\lambda$$

Since the hazard rate is constant, the item does not age. Its reliability does not decrease over time.

## Section 3.5: Expected Values

$$3.5.1 \quad E(X) = -1(0.935) + 2(0.0514) + 18(0.0115) + 180(0.0016) + 1,300(1.35 \times 10^{-4}) \\ + 2,600(6.12 \times 10^{-6}) + 10,000(1.12 \times 10^{-7}) = -0.144668$$

$$3.5.2 \quad \text{Let } X \text{ be the winnings of betting on red in Monte Carlo. Then } E(X) = \frac{18}{37} - \frac{19}{37} = \frac{-1}{37}.$$

$$\text{Let } X^* \text{ be the winnings of betting on red in Las Vegas. Then } E(X) = \frac{18}{38} - \frac{20}{38} = \frac{-2}{38}.$$

The amount bet,  $M$ , is the solution to the equation  $M \left( \frac{-1}{37} - \frac{-2}{38} \right) = \$3,000$  or  $M$  is

approximately equal to \$117,167

$$\begin{aligned}
 3.5.3 \quad E(X) &= \$30,000(0.857375) + \$18,000(0.135375) + \$6,000(0.007125) + (-\$6,000)(0.000125) \\
 &= \$28,200.00
 \end{aligned}$$

$$3.5.4 \quad \text{Rule A: Expected value} = -5 + 0 \cdot \frac{\binom{2}{0}\binom{4}{2}}{\binom{6}{2}} + 2 \cdot \frac{\binom{2}{1}\binom{4}{1}}{\binom{6}{2}} + 10 \cdot \frac{\binom{2}{2}\binom{4}{0}}{\binom{6}{2}} = -49/15$$

$$\text{Rule B: Expected value} = -5 + 0 \cdot \frac{\binom{2}{0}\binom{4}{2}}{\binom{6}{2}} + 1 \cdot \frac{\binom{2}{1}\binom{4}{1}}{\binom{6}{2}} + 20 \cdot \frac{\binom{2}{2}\binom{4}{0}}{\binom{6}{2}} = -47/15$$

Neither game is fair to the player, but Rule B has the better payoff.

$$\begin{aligned}
 3.5.5 \quad P \text{ is the solution to the equation } \sum_{i=1}^5 [P(1-p_k) - 50,000p_k] &= P \sum_{i=1}^5 (1-p_k) - 50,000 \sum_{i=1}^5 p_k \\
 &= 1000, \text{ where } p_k \text{ is the probability of death in year } k, k = 1, 2, 3, 4, 5. \text{ Now } \sum_{i=1}^5 p_k = 0.00272 \\
 \text{and } \sum_{i=1}^5 (1-p_k) &= 4.99728, \text{ so the equation becomes } 4.99728P - 50,000(0.00272) = 1000, \text{ or} \\
 P &= \$227.32.
 \end{aligned}$$

3.5.6 The random variable  $X$  is hypergeometric, where  $r = 4$ ,  $w = 96$ ,  $n = 20$ .

$$\text{Then } E(X) = \frac{4(20)}{4+96} = \frac{4}{5}.$$

3.5.7 This is a hypergeometric problem where  $r$  = number of students needing vaccinations = 125 and  $w$  = number of students already vaccinated =  $642 - 125 = 517$ . An absenteeism rate of 12% corresponds to a sample  $n = (0.12)(642)$  is approximately 77 missing students. The expected number of unvaccinated students who are absent when the physician visits is  $\frac{125(77)}{125+517}$ , or approximately 15.

$$3.5.8 \quad (a) \ E(Y) = \int_0^1 y \cdot 3(1-y)^2 dy = \int_0^1 3(y-2y^2+y^3) dy = 3 \left[ \frac{1}{2}y^2 - \frac{2}{3}y^3 + \frac{1}{4}y^4 \right]_0^1 = \frac{1}{4}$$

$$(b) \ E(Y) = \int_0^\infty y \cdot 4ye^{-2y} dy = 4 \left[ -\frac{1}{2}y^2e^{-2y} - \frac{1}{2}ye^{-2y} - \frac{1}{4}e^{-2y} \right]_0^\infty = 1$$

$$(c) \ E(Y) = \int_0^1 y \cdot \left(\frac{3}{4}\right) dy + \int_2^3 y \cdot \left(\frac{1}{4}\right) dy = \frac{3y^2}{8} \Big|_0^1 + \frac{y^2}{8} \Big|_2^3 = 1$$

$$(d) \ E(Y) = \int_0^{\pi/2} y \cdot \sin y dy = (-y \cos y + \sin y) \Big|_0^{\pi/2} = 1$$

$$3.5.9 \quad E(Y) = \int_0^3 y \left( \frac{1}{9}y^2 \right) dy = \frac{1}{9} \int_0^3 y^3 dy = \frac{y^4}{36} \Big|_0^3 = \frac{9}{4} \text{ years}$$

$$3.5.10 \quad E(Y) = \int_a^b y \frac{1}{b-a} dy = \frac{y^2}{2(b-a)} \Big|_a^b = \frac{b^2}{2(b-a)} - \frac{a^2}{2(b-a)} = \frac{b+a}{2}. \quad \text{This simply says that a uniform bar will balance at its middle.}$$

$$3.5.11 \quad E(Y) = \int_0^\infty y \cdot \lambda e^{-\lambda y} dy = \left( -ye^{-\lambda y} - \frac{1}{\lambda}e^{-\lambda y} \right) \Big|_0^\infty = \frac{1}{\lambda}$$

$$3.5.12 \quad \text{Since } \frac{1}{y^2} \geq 0, \text{ this function will be a pdf if its integral is 1, and } \int_1^\infty \frac{1}{y^2} dy = -\frac{1}{y} \Big|_1^\infty = 1.$$

However, what would be its expected value is  $\int_1^\infty y \frac{1}{y^2} dy = \int_1^\infty \frac{1}{y} dy = \ln y \Big|_1^\infty$ , but this last quantity is infinite.

3.5.13 Let  $X$  be the number of cars passing the emissions test. Then  $X$  is binomial with  $n = 200$  and  $p = 0.80$ . Two formulas for  $E(X)$  are:

$$(1) \ E(X) = \sum_{k=1}^n k \binom{n}{k} p^k (1-p)^{n-k} = \sum_{k=1}^{200} k \binom{200}{k} (0.80)^k (0.20)^{200-k}$$

$$(2) \ E(X) = np = 200(0.80) = 160$$

**3.5.14** The probability that an observation of  $Y$  lies in the interval  $(1/2, 1)$  is  $\int_{1/2}^1 3y^2 dy = y^3 \Big|_{1/2}^1 = \frac{7}{8}$ .

Then  $X$  is binomial with  $n = 15$  and  $p = 7/8$ .  $E(X) = 15(7/8) = 105/8$ .

**3.5.15** If birthdays are randomly distributed throughout the year, the city should expect revenue of  $(\$50)(74,806)(30/365)$  or \$307,421.92.

**3.5.16** If we assume that the probability of bankruptcy due to fraud is  $23/68$ , then we can expect  $9(23/68) = 3.04$ , or roughly 3 of the 9 additional bankruptcies will be due to fraud.

**3.5.17** For the experiment described, construct the table:

Sample	Larger of the two, $k$
1, 2	2
1, 3	3
1, 4	4
2, 3	3
2, 4	4
3, 4	4

Each of the six samples is equally likely to be drawn, so  $p_X(2) = 1/6$ ,  $p_X(3) = 2/6$ , and  $p_X(4) = 3/6$ . Then  $E(X) = 2(1/6) + 3(2/6) + 4(3/6) = 20/6 = 10/3$ .

**3.5.18**

Outcome	$X$
HHH	6
HHT	2
HTH	4
HTT	1
THH	2
THT	0
TTH	1
TTT	0

From the table, we can calculate  $p_X(0) = 1/4$ ,  $p_X(1) = 1/4$ ,  $p_X(2) = 1/4$ ,  $p_X(4) = 1/8$ ,  $p_X(6) = 1/8$ .

Then  $E(X) = 0 \cdot (1/4) + 1 \cdot (1/4) + 2 \cdot (1/4) + 4 \cdot (1/8) + 6 \cdot (1/8) = 2$ .

**3.5.19** The “fair” ante is the expected value of  $X$ , which is

$$\sum_{k=1}^9 2^k \left( \frac{1}{2^k} \right) + \sum_{k=10}^{\infty} 1000 \left( \frac{1}{2^k} \right) = 9 + \frac{1000}{2^{10}} \sum_{k=0}^{\infty} \left( \frac{1}{2^k} \right) = 9 + \frac{1000}{2^{10}} \frac{1}{1 - \frac{1}{2}} = 9 + \frac{1000}{512} = \frac{5608}{512}$$

= \$10.95

**3.5.20** (a)  $E(X) = \sum_{k=1}^{\infty} c^k \left( \frac{1}{2} \right)^k = \sum_{k=1}^{\infty} \left( \frac{c}{2} \right)^k = \frac{c}{2} \sum_{k=0}^{\infty} \left( \frac{c}{2} \right)^k = \frac{c}{2-c}$

(b)  $\sum_{k=1}^{\infty} \log 2^k \left( \frac{1}{2} \right)^k = \log 2 \sum_{k=1}^{\infty} k \left( \frac{1}{2} \right)^k$

To evaluate the sum requires a special technique:

For a parameter  $t$ ,  $0 < t < 1$ , note that  $\sum_{k=1}^{\infty} t^k = \frac{t}{1-t}$ .

Differentiate both sides of the equation with respect to  $t$  to obtain  $\sum_{k=1}^{\infty} k t^{k-1} = \frac{1}{(1-t)^2}$ .

Multiplying both sides by  $t$  gives the desired equation:  $\sum_{k=1}^{\infty} k t^k = \frac{t}{(1-t)^2}$ .

In the case of interest,  $t = 1/2$ , so  $\sum_{k=1}^{\infty} k \left( \frac{1}{2} \right)^k = 2$ , and  $E(X) = 2 \cdot \log 2$ .

**3.5.21**  $p_X(1) = \frac{6}{216} = \frac{1}{36}$

$$p_X(2) = \frac{3(6)(5)}{216} = \frac{15}{36}$$

$$p_X(3) = \frac{6(5)(4)}{216} = \frac{20}{36}$$

$$E(X) = 1 \cdot \frac{1}{36} + 2 \cdot \frac{15}{36} + 3 \cdot \frac{20}{36} = \frac{91}{36}$$

**3.5.22** For the experiment described, construct the table

Sample	Absolute value of difference
1, 2	1
1, 3	2
1, 4	3
1, 5	4
2, 3	1
2, 4	2
2, 5	3
3, 4	1
3, 5	2
4, 5	1

If  $X$  denotes the absolute value of the difference, then from the table:

$$p_X(1) = 4/10, p_X(2) = 3/10, p_X(3) = 2/10, p_X(4) = 1/10$$

$$E(X) = 1(4/10) + 2(3/10) + 3(2/10) + 4(1/10) = 2$$

**3.5.23** Let  $X$  be the length of the series. Then  $p_X(k) = 2 \binom{k-1}{3} \left(\frac{1}{2}\right)^k$ ,  $k = 4, 5, 6, 7$ .

$$E(X) = \sum_{k=4}^7 (k)(2) \binom{k-1}{3} \left(\frac{1}{2}\right)^k = 4 \left(\frac{2}{16}\right) + 5 \left(\frac{4}{16}\right) + 6 \left(\frac{5}{16}\right) + 7 \left(\frac{5}{16}\right) = \frac{93}{16} = 5.8125$$

**3.5.24** Let  $X$  = number of drawings to obtain a white chip. Then  $p_X(k) = \frac{1}{k} \cdot \frac{1}{k+1}$ ,  $k = 1, 2, \dots$

$$E(X) = \sum_{k=1}^{\infty} k \left( \frac{1}{k(k+1)} \right) = \sum_{k=1}^{\infty} \frac{1}{k+1}.$$

$$\text{For each } n, \text{ let } T_n = \sum_{i=2^n}^{i=2^{n+1}} \frac{1}{i}. \text{ Then } T_n \geq \frac{2^n}{2^{n+1}} = \frac{1}{2}.$$

$$\sum_{k=1}^{\infty} \frac{1}{k+1} \geq \sum_{n=1}^{\infty} T_n = \frac{1}{2} + \frac{1}{2} + \frac{1}{2} + \dots \quad \text{This last sum is infinite, so } E(X) \text{ does not exist.}$$

$$3.5.25 \quad E(X) = \sum_{k=1}^r k \frac{\binom{r}{k} \binom{w}{n-k}}{\binom{r+w}{n}} = \sum_{k=1}^r k \frac{\frac{r!}{k!(r-k)!} \binom{w}{n-k}}{\frac{(r+w)!}{n!(r+w-n)!}}$$

Factor out the presumed value of  $E(X) = rn/(r+w)$ :

$$E(X) = \frac{rn}{r+w} \sum_{k=1}^r \frac{\frac{(r-1)!}{(k-1)!(r-k)!} \binom{w}{n-k}}{\frac{(r-1+w)!}{(n-1)!(r+w-n)!}} = \frac{rn}{r+w} \sum_{k=1}^r \frac{\binom{r-1}{k-1} \binom{w}{n-k}}{\binom{r-1+w}{n-1}}$$

Change the index of summation to begin at 0, which gives

$$E(X) = \frac{rn}{r+w} \sum_{k=0}^{r-1} \frac{\binom{r-1}{k} \binom{w}{n-1-k}}{\binom{r-1+w}{n-1}}.$$

The terms of the summation are urn probabilities where there are  $r-1$  red balls,  $w$  white balls, and a sample size of  $n-1$  is drawn. Since these are the probabilities of a hypergeometric pdf,

the sum is one. This leaves us with the desired equality  $E(X) = \frac{rn}{r+w}$ .

$$3.5.26 \quad E(X) = \sum_{j=1}^{\infty} j p_X(j) = \sum_{j=1}^{\infty} \sum_{k=1}^j p_X(j) = \sum_{k=1}^{\infty} \sum_{j=k}^{\infty} p_X(j) = \sum_{k=1}^{\infty} P(X \geq k)$$

$$3.5.27 \quad (a) \quad 0.5 = \int_0^1 (\theta+1)y^\theta dy = y^{\theta+1} \Big|_0^1 = m^{\theta+1}, \text{ so } m = (0.5)^{\frac{1}{\theta+1}}$$

$$(b) \quad 0.5 = \int_0^1 \left(y + \frac{1}{2}\right) dy = \left(\frac{y^2}{2} + \frac{y}{2}\right) \Big|_0^1 = \frac{m^2}{2} + \frac{m}{2}. \text{ Solving the quadratic equation}$$

$$\frac{1}{2}(m^2 + m - 1) = 0 \text{ gives } m = \frac{-1 + \sqrt{5}}{2}.$$

$$3.5.28 \quad E(3X - 4) = 3E(X) - 4 = 3(10)(2/5) - 4 = 8$$

$$3.5.29 \quad \$100(12)(0.11) = \$132$$

$$3.5.30 \quad E(W) = \int_0^1 w \left( \frac{1}{\sqrt{w}} - 1 \right) dw = \left( \frac{2}{3} w^{3/2} - \frac{w^2}{2} \right) \Big|_0^1 = 1/6$$

$$\text{Also, } E(W) = E(Y^2) = \int_0^1 y^2 [2(1-y)] dy = \left( \frac{2}{3} y^3 - \frac{2}{4} y^4 \right) \Big|_0^1 = 1/6.$$

$$3.5.31 \quad E(Q) = \int_0^\infty 2(1 - e^{-2y}) 6e^{-6y} dy = 12 \int_0^\infty (e^{-6y} - e^{-8y}) dy = 12 \left[ -\frac{1}{6} e^{-6y} + \frac{1}{8} e^{-8y} \right]_0^\infty = \frac{1}{2}, \text{ or } \$50,000$$

$$3.5.32 \quad E(\text{Volume}) = \int_0^\infty 5y^2 6y(1-y) dy = 30 \int_0^1 (y^3 - y^4) dy = 30 \left[ \frac{1}{4} y^4 - \frac{1}{5} y^5 \right]_0^1 = 1.5 \text{ in}^3$$

$$3.5.33 \quad \begin{aligned} \text{Class average} &= E(g(Y)) = \int_0^{100} 10y^{1/2} \frac{1}{5000} (100-y) dy \\ &= \frac{1}{500} \int_0^1 (100y^{1/2} - y^{3/2}) dy = \frac{1}{500} \left[ \frac{2}{3} 100y^{3/2} - \frac{2}{5} y^{5/2} \right]_0^{100} \\ &= 53.3, \text{ so the professor's "curve" did not work.} \end{aligned}$$

$$3.5.34 \quad E(W) = \int_0^1 \left( y - \frac{2}{3} \right)^2 (2y) dy = 2 \left( \frac{1}{4} y^4 - \frac{4}{9} y^3 + \frac{2}{9} y^2 \right) \Big|_0^1 = 1/36$$

$$3.5.35 \quad \text{The area of the triangle} = \frac{1}{4} y^2, \text{ so } E(\text{Area}) = \int_6^{10} \frac{1}{4} y^2 \frac{1}{10-6} dy = \frac{1}{16} \frac{y^3}{3} \Big|_6^{10} = 16.33.$$

$$3.5.36 \quad 1 = \sum_{i=1}^n ki = k \frac{n(n+1)}{2} \text{ implies } k = \frac{2}{n(n+1)}$$

$$E\left(\frac{1}{X}\right) = \sum_{i=1}^n \frac{1}{i} \frac{2}{n(n+1)} i = 2/(n+1)$$

## Section 3.6: The Variance

- 3.6.1** If sampling is done with replacement,  $X$  is binomial with  $n = 2$  and  $p = 2/5$ . By Theorem 3.5.1,  $\mu = 2(2/5) = 4/5$ .  $E(X^2) = 0 \cdot (9/25) + 1 \cdot (12/25) + 4 \cdot (4/25) = 28/25$ . Then  $\text{Var}(X) = 28/25 - (4/5)^2 = 12/25$ .

**3.6.2**

$$\mu = \int_0^1 y \left( \frac{3}{4} \right) dy + \int_2^3 y \left( \frac{1}{4} \right) dy = 1$$

$$E(X^2) = \int_0^1 y^2 \left( \frac{3}{4} \right) dy + \int_2^3 y^2 \left( \frac{1}{4} \right) dy = \frac{11}{6}$$

$$\text{Var}(X) = \frac{11}{6} - 1 = \frac{5}{6}$$

- 3.6.3** Since  $X$  is hypergeometric,  $\mu = \frac{3(6)}{10} = \frac{9}{5}$

$$E(X^2) = \sum_{k=0}^3 k^2 \frac{\binom{6}{k} \binom{4}{3-k}}{\binom{10}{3}} = 0 \cdot (4/120) + 1 \cdot (36/120) + 4 \cdot (60/120) + 9 \cdot (20/120)$$

$$= 456/120 = 38/10$$

$$\text{Var}(X) = 38/10 - (9/5)^2 = 28/50 = 0.56, \text{ and } \sigma = 0.748$$

**3.6.4**

$$E(X) = \$250 \cdot \frac{1}{15}[(5 + 4 + 3)] + \$150 \cdot \frac{1}{15}[(2 + 1)] = \$200 + \$30 = \$230$$

$$E(X^2) = \$250^2 \cdot \frac{1}{15}[(5 + 4 + 3)] + \$150^2 \cdot \frac{1}{15}[(2 + 1)] = \$50,000 + \$4500 = \$54,500$$

$$\text{Var}(X) = \$54,500 - \$230^2 = \$1600$$

$$3.6.5 \quad \mu = \int_0^1 y 3(1-y)^2 dy = 3 \int_0^1 (y - 2y^2 + y^3) dy = 1/4$$

$$E(Y^2) = \int_0^1 y^2 3(1-y)^2 dy = 3 \int_0^1 (y^2 - 2y^3 + y^4) dy = 1/10$$

$$\text{Var}(Y) = 1/10 - (1/4)^2 = 3/80$$

$$3.6.6 \quad \mu = \int_0^k y \frac{2y}{k^2} dy = \frac{2k}{3}. \quad E(Y^2) = \int_0^k y^2 \frac{2y}{k^2} dy = \frac{k^2}{2}$$

$$\text{Var}(Y) = \frac{k^2}{2} - \left(\frac{2k}{3}\right)^2 = \frac{k^2}{18}. \quad \text{Var}(Y) = 2 \text{ implies } \frac{k^2}{18} = 2 \text{ or } k = 6.$$

$$3.6.7 \quad f_Y(y) = \begin{cases} 1-y, & 0 \leq y \leq 1 \\ 1/2, & 2 \leq y \leq 3 \\ 0, & \text{elsewhere} \end{cases}$$

$$\mu = \int_0^1 y(1-y) dy + \int_2^3 y \left(\frac{1}{2}\right) dy = 17/12$$

$$E(Y^2) = \int_0^1 y^2(1-y) dy + \int_2^3 y^2 \left(\frac{1}{2}\right) dy = 13/4$$

$$\sigma = \sqrt{13/4 - (17/12)^2} = \sqrt{179}/12 = 1.115$$

$$3.6.8 \quad (a) \quad \int_1^\infty \frac{2}{y^3} dy = \frac{-1}{y^2} \Big|_1^\infty = 1$$

$$(b) \quad E(Y) = \int_1^\infty y \frac{2}{y^3} dy = \frac{-2}{y} \Big|_1^\infty = 2$$

$$(c) \quad E(Y^2) = \int_1^\infty y^2 \frac{2}{y^3} dy = 2 \ln y \Big|_1^\infty, \text{ which is infinite.}$$

3.6.9 Let  $Y$  = Frankie's selection. Johnny wants to choose  $k$  so that  $E[(Y - k)^2]$  is minimized. The minimum occurs when  $k = E(Y) = (a + b)/2$  (see Question 3.6.13).

$$3.6.10 \quad E(Y) = \int_0^1 y(5y^4)dy = 5 \int_0^1 y^5 dy = \frac{5}{6} y^6 \Big|_0^1 = \frac{5}{6}$$

$$E(Y^2) = \int_0^1 y^2(5y^4)dy = 5 \int_0^1 y^6 dy = \frac{5}{7} y^7 \Big|_0^1 = \frac{5}{7}$$

$$\text{Var}(Y) = E(Y^2) - E(Y)^2 = \frac{5}{7} - \left(\frac{5}{6}\right)^2 = \frac{5}{7} - \frac{25}{36} = \frac{5}{252}$$

3.6.11 Using integration by parts, we find that

$$E(Y^2) = \int_0^\infty y^2 \lambda e^{-\lambda y} dy = -y^2 e^{-\lambda y} \Big|_0^\infty + \int_0^\infty 2y e^{-\lambda y} dy = 0 + \int_0^\infty 2y e^{-\lambda y} dy,$$

$$\text{The right hand term is } 2 \int_0^\infty y e^{-\lambda y} dy = \frac{2}{\lambda} \int_0^\infty y \lambda e^{-\lambda y} dy = \frac{2}{\lambda} E(Y) = \frac{2}{\lambda} \frac{1}{\lambda} = \frac{2}{\lambda^2}.$$

$$\text{Then } \text{Var}(Y) = E(Y^2) - E(Y)^2 = \frac{2}{\lambda^2} - \left(\frac{1}{\lambda}\right)^2 = \frac{1}{\lambda^2}.$$

3.6.12 For the given  $Y$ ,  $E(Y) = 1/2$  and  $\text{Var}(Y) = 1/4$ .

$$\begin{aligned} \text{Then } P\left(Y > E(Y) + 2\sqrt{\text{Var}(Y)}\right) &= P\left(Y > \frac{1}{2} + 2\sqrt{\frac{1}{4}}\right) = P\left(Y > \frac{3}{2}\right) \\ &= \int_{3/2}^\infty 2e^{-2y} dy = 1 - \int_\infty^{3/2} 2e^{-2y} dy = 1 - (1 - e^{-2(3/2)}) = e^{-3} = 0.0498 \end{aligned}$$

$$3.6.13 \quad E[(X - a)^2] = E[((X - \mu) + (\mu - a))^2] = E[(X - \mu)^2] + E[(\mu - a)^2] + 2(\mu - a)E(X - \mu) \\ = \text{Var}(X) + (\mu - a)^2, \text{ since } E(X - \mu) = 0.$$

This is minimized when  $a = \mu$ , so the minimum of  $g(a) = \text{Var}(X)$ .

3.6.14 Let  $Y$  be the cost of repairs. Given  $E(Y) = \$200$  and  $\sigma(Y) = \$16$ . The total charge to the customer is  $W = X + 0.1X + 15 = 1.1X + 15$ .

$$\text{Then } \text{Var}(W) = 1.1^2 \text{Var}(Y) = 1.21(16^2) = 309.76, \text{ and } \sigma(W) = \sqrt{309.76} = \$17.6$$

$$\mathbf{3.6.15} \quad \text{Var}\left(\frac{5}{9}(Y-32)\right) = \left(\frac{5}{9}\right)^2 \text{Var}(Y), \text{ by Theorem 3.6.2.}$$

$$\text{So } \sigma\left(\frac{5}{9}(Y-32)\right) = \left(\frac{5}{9}\right)\sigma(Y) = \frac{5}{9}(15.7) = 8.7^\circ\text{C}.$$

$$\mathbf{3.6.16} \quad (1) E[(W - \mu)/\sigma] = (1/\sigma)E[(W - \mu)] = 0$$

$$(2) \text{Var}[(W - \mu)/\sigma] = (1/\sigma^2)\text{Var}[(W - \mu)] = (1/\sigma^2)\sigma^2 = 1$$

$$\mathbf{3.6.17} \quad (\text{a}) f_Y(y) = \frac{1}{b-a} f_U\left(\frac{y-a}{b-a}\right) = \frac{1}{b-a}, (b-a)(0) + a \leq y \leq (b-a)(1) + a, \text{ or}$$

$$f_Y(y) = \frac{1}{b-a}, a \leq y \leq b, \text{ which is the uniform pdf over } [a, b]$$

$$(\text{b}) \text{Var}(Y) = \text{Var}[(b-a)U + a] = (b-a)^2 \text{Var}(U) = (b-a)^2/12$$

$$\mathbf{3.6.18} \quad E(Y) = 5.5 \text{ and } \text{Var}(Y) = 0.75.$$

$$E(W_1) = 0.2281 + (0.9948)E(Y) + E(E_1) = 0.2281 + (0.9948)(5.5) + 0 = 5.6995$$

$$E(W_2) = -0.0748 + (1.0024)E(Y) + E(E_2) = -0.0748 + (1.0024)(5.5) + 0 = 5.4384$$

$$\text{Var}(W_1) = (0.9948)^2 \text{Var}(Y) + \text{Var}(E_1) = (0.9948)^2(0.75) + 0.0427 = 0.7849$$

$$\text{Var}(W_2) = (1.0024)^2 \text{Var}(Y) + \text{Var}(E_2) = (1.0024)^2(0.75) + 0.0159 = 0.7695$$

So the second procedure is better, since the mean of  $W_2$  is closer to the true mean, and it has smaller variance.

$$\mathbf{3.6.19} \quad E(Y^r) = \int_0^2 y^r \frac{1}{2} dy = \frac{1}{2} \frac{y^{r+1}}{r+1} \Big|_0^2 = \frac{2^r}{r+1}$$

$$E[(Y-1)^6] = \sum_{j=0}^6 \binom{6}{j} E(Y^j) (-1)^{6-j} = \sum_{j=0}^6 \binom{6}{j} \frac{2^j}{j+1} (-1)^{6-j}$$

$$= (1)(1) + (-6)(1) + 15(4/3) + (-20)(2) + (15)(16/5) + (-6)(32/6) + (1)(64/7) = 1/7$$

$$\mathbf{3.6.20} \quad \text{For the given } f_Y, \mu = 1 \text{ and } \sigma = 1.$$

$$\mathcal{H} = \frac{E[(Y-1)^3]}{1} = \sum_{j=0}^3 \binom{3}{j} E(Y^j) (-1)^{3-j} = \sum_{j=0}^3 \binom{3}{j} (j!) (-1)^{3-j}$$

$$(1)(1)(-1) + (3)(1)(1) + (3)(2)(-1) + (1)(6)(1) = 2$$

**3.6.21** For the uniform random variable  $U$ ,  $E(U) = 1/2$  and  $\text{Var}(U) = 1/12$ . Also the  $k$ -th moment of  $U$

$$\text{is } E(U^k) = \int_0^1 u^k du = \frac{1}{k+1}.$$

$$\begin{aligned} \text{Then first find } \frac{E[(U - \mu)^4]}{\sigma^4} - 3 &= \frac{E[(U - \mu)^4]}{\text{Var}^2(U)} = \frac{E[(U - 1/2)^4]}{(1/12)^2} = (144) \sum_{k=0}^4 \binom{4}{k} \frac{1}{k+1} \left(-\frac{1}{2}\right)^{4-k} \\ &= 9/5 \end{aligned}$$

The coefficient of kurtosis  $\gamma_2 = 9/5 - 3 = -6/5$

$$\begin{aligned} \frac{E[(U - \mu)^4]}{\sigma^4} - 3 &= \frac{E[(U - \mu)^4]}{\text{Var}^2(U)} = \frac{E[(U - 1/2)^4]}{(1/12)^2} = (144) \sum_{k=0}^4 \binom{4}{k} \frac{1}{k+1} \left(-\frac{1}{2}\right)^{4-k} \\ &= (144)(1/80) = 9/5 \end{aligned}$$

**3.6.22**  $10 = E[(W - 2)^3] = \sum_{j=0}^3 \binom{3}{j} E(W^j)(-2)^{3-j} = (1)(1)(-8) + (3)(2)(4) + (3)E(W^2)(-2) + (1)(4)(1).$

This would imply that  $E(W^2) = 5/3$ . In that case,  $\text{Var}(W) = 5/3 - (2)^2 < 0$ , which is not possible.

**3.6.23** Let  $E(X) = \mu$ ; let  $\sigma$  be the standard deviation of  $X$ . Then  $E(aX + b) = a\mu + b$ .

Also,  $\text{Var}(aX + b) = a^2 \sigma^2$ , so the standard deviation of  $aX + b = a\sigma$ .

$$\text{Then } \gamma_1 = \frac{E[((aX + b) - (a\mu + b))^3]}{(a\sigma)^3} = \frac{a^3 E[(X - \mu)^3]}{a^3 \sigma^3} = \frac{E[(X - \mu)^3]}{\sigma^3} = \gamma_1(X)$$

The demonstration for  $\gamma_2$  is similar.

**3.6.24** (a) Question 3.4.6 established that  $Y$  is a pdf for any positive integer  $n$ . As a corollary, we

know that  $1 = \int_0^1 (n+2)(n+1)y^n(1-y)dy$  or equivalently, for any positive integer  $n$ ,

$$\int_0^1 y^n(1-y)dy = \frac{1}{(n+2)(n+1)}$$

$$\text{Then } E(Y^2) = \int_0^1 y^n (n+2)(n+1)y^n(1-y)dy = (n+2)(n+1) \int_0^1 y^{n+2}(1-y)dy$$

$$= \frac{(n+2)(n+1)}{(n+4)(n+3)}. \text{ By a similar argument, } E(Y) = \frac{(n+2)(n+1)}{(n+4)(n+3)} = \frac{(n+1)}{(n+3)}.$$

$$\text{Thus, } \text{Var}(Y) = E(Y^2) - E(Y)^2 = \frac{(n+2)(n+1)}{(n+4)(n+3)} - \frac{(n+1)^2}{(n+3)^2} = \frac{2(n+1)}{(n+4)(n+3)^2}$$

$$(b) E(Y^k) = \int_0^1 y^k (n+2)(n+1)y^n(1-y)dy = (n+2)(n+1) \int_0^1 y^{n+k}(1-y)dy$$

$$= \frac{(n+2)(n+1)}{(n+k+2)(n+k+1)}$$

$$3.6.25 \quad (a) 1 = \int_1^\infty cy^{-6}dy = c \left[ \frac{y^{-5}}{-5} \right]_1^\infty = c \frac{1}{5}, \text{ so } c = 5.$$

$$(b) E(Y^r) = 5 \int_1^\infty y^r y^{-6}dy = 5 \left[ \frac{y^{r-5}}{r-5} \right]_1^\infty. \text{ For this last expression to be finite, } r \text{ must be } < 5.$$

The highest integral moment is  $r = 4$ .

## Section 3.7: Joint Densities

$$3.7.1 \quad 1 = \sum_{x,y} p(x,y) = c \sum_{x,y} xy = c[(1)(1) + (2)(1) + (2)(2) + (3)(1)] = 10c, \text{ so } c = 1/10$$

$$3.7.2 \quad 1 = \int_0^1 \int_0^1 c(x^2 + y^2)dx dy = c \int_0^1 \int_0^1 x^2 dx dy + c \int_0^1 \int_0^1 y^2 dy dx$$

$$= c \int_0^1 \left[ \frac{x^3}{3} \right]_0^1 dy + c \int_0^1 \left[ \frac{y^3}{3} \right]_0^1 dx = c \int_0^1 \frac{1}{3} dy + c \int_0^1 \frac{1}{3} dx = \frac{2}{3}c, c = 3/2.$$

$$3.7.3 \quad 1 = \int_0^1 \int_0^y c(x+y)dx dy = c \int_0^1 \left[ \frac{x^2}{2} + xy \right]_0^y dy = c \int_0^1 \frac{3y^2}{2} dy = c \left[ \frac{y^3}{2} \right]_0^1 = \frac{c}{2}, \text{ so } c = 2.$$

$$3.7.4 \quad 1 = c \int_0^1 \left( \int_0^y xy dx \right) dy = c \int_0^1 \left[ \frac{x^2 y}{2} \right]_0^y dy = c \int_0^1 \frac{y^3}{2} dy$$

$$c \left[ \frac{y^4}{8} \right]_0^1 = c \left( \frac{1}{8} \right), \text{ so } c = 8$$

$$3.7.5 \quad P(X=x, Y=y) = \frac{\binom{3}{x} \binom{2}{y} \binom{4}{3-x-y}}{\binom{9}{3}}, 0 \leq x \leq 3, 0 \leq y \leq 2, x+y \leq 3$$

$$3.7.6 \quad P(X=x, Y=y) = \frac{\binom{4}{x} \binom{4}{y} \binom{44}{4-x-y}}{\binom{52}{4}}, 0 \leq x \leq 4, 0 \leq y \leq 4, x+y \leq 4$$

$$3.7.7 \quad P(X > Y) = p_{X,Y}(1, 0) + p_{X,Y}(2, 0) + p_{X,Y}(2, 1) = 6/50 + 4/50 + 3/50 = 13/50$$

3.7.8

Outcome	$X$	$Y$
H H H	1	3
H H T	0	2
H T H	1	2
H T T	0	1
T H H	1	2
T H T	0	1
T T H	1	1
T T T	0	0

$(x, y)$	$p_{X,Y}(x, y)$
(0, 0)	1/8
(0, 1)	2/8
(0, 2)	1/8
(0, 3)	0
(1, 0)	0
(1, 1)	1/8
(1, 2)	2/8
(1, 3)	1/8

## 3.7.9

		Number of 2's, $X$		
		0	1	2
Number of 3's, $Y$	0	16/36	8/36	1/36
	1	8/36	2/36	0
	2	1/36	0	0

From the matrix above, we calculate

$$p_Z(0) = p_{X,Y}(0, 0) = 16/36$$

$$p_Z(1) = p_{X,Y}(0, 1) + p_{X,Y}(1, 0) = 2(8/36) = 16/36$$

$$p_Z(2) = p_{X,Y}(0, 2) + p_{X,Y}(2, 0) + p_{X,Y}(1, 1) = 4/36$$

**3.7.10** (a)  $1 = \int_0^7 \int_0^7 c \, dx dy = \int_0^7 \left( cx \Big|_0^7 \right) dy = 7c \cdot \int_0^7 dy = 49c$ , so  $c = 1/49$

(b)  $P(0 \leq X \leq 2, 0 \leq Y \leq 4) = \int_0^4 \int_0^2 1/49 \, dx dy = 8/49$

$$\begin{aligned}
3.7.11 \quad P(Y < 3X) &= \int_{-\infty}^{\infty} \int_x^{3x} 2e^{-(x+y)} dy dx = \int_{-\infty}^{\infty} e^{-x} \left( \int_x^{3x} 2e^{-y} dy \right) dx \\
&= 2 \int_{-\infty}^{\infty} e^{-x} \left( \left[ -e^{-y} \right]_x^{3x} \right) dx = 2 \int_{-\infty}^{\infty} e^{-x} \left[ e^{-x} - e^{-3x} \right] dx \\
&= 2 \int_0^{\infty} \left[ e^{-2x} - e^{-4x} \right] dx = 2 \left[ -\frac{1}{2} e^{-2x} + \frac{1}{4} e^{-4x} \right]_0^{\infty} = \frac{1}{2}
\end{aligned}$$

3.7.12 The density is the bivariate uniform over a circle of radius 2.  
The area of the circle is  $\pi(2)^2 = 4\pi$ . Thus,  $f_{X,Y}(x, y) = 1/4\pi$ .

$$\begin{aligned}
3.7.13 \quad P(X < 2Y) &= \int_0^1 \int_{x/2}^1 (x+y) dy dx \\
&= \int_0^1 \int_{x/2}^1 x dy dx + \int_0^1 \int_{x/2}^1 y dy dx \\
&= \int_0^1 \left[ x - \frac{x^2}{2} \right] dx + \int_0^1 \left[ \frac{1}{2} - \frac{x^2}{8} \right] dx \\
&= \left[ \frac{x^2}{2} - \frac{x^3}{6} \right]_0^1 + \left[ \frac{x}{2} - \frac{x^3}{24} \right]_0^1 = \frac{19}{24}
\end{aligned}$$

3.7.14 The probability of an observation falling into the interval  $(0, 1/3)$  is  $\int_0^{1/3} 2t dt = 1/9$ .

The probability of an observation falling into the interval  $(1/3, 2/3)$  is  $\int_{1/3}^{2/3} 2t dt = 1/3$ .

Assume without any loss of generality that the five observations are done in order. To calculate  $p_{X,Y}(1, 2)$ , note that there are  $\binom{5}{1}$  places where the observation in  $(0, 1/3)$  could occur, and  $\binom{4}{2}$  choices for the location of the observations in  $(1/3, 2/3)$ .

Then  $p_{X,Y}(1, 2) = \binom{5}{1} \binom{4}{2} (1/9)^1 (1/3)^2 (5/9)^2 = 750/6561$ .

**3.7.15** The set where  $y > h/2$  is a triangle with height  $h/2$  and base  $b/2$ . Its area is  $bh/8$ . Thus the area of the set where  $y < h/2$  is  $bh/2 - bh/8 = 3bh/8$ . The probability that a randomly chosen point will fall in the lower half of the triangle is  $(3bh/8)/(bh/2) = 3/4$ .

$$\mathbf{3.7.16} \quad p_X(x) = \frac{\binom{3}{x}}{\binom{9}{3}} \sum_{y=0}^{\min(2, 3-x)} \binom{2}{y} \binom{4}{3-x-y} = \frac{\binom{3}{x} \binom{6}{3-x}}{\binom{9}{3}}, x=0,1,2,3$$

**3.7.17** From the solution to Question 3.7.8,  $p_X(x) = 1/8 + 2/8 + 1/8 = 1/2$ ,  $x = 0, 1$ ,  $p_Y(0) = 1/8$ ,  $p_Y(1) = 3/8$ ,  $p_Y(2) = 3/8$ ,  $p_Y(3) = 1/8$ .

**3.7.18** Let  $X_1$  be the number in the upper quarter;  $X_2$ , the number in the middle half. From Question 3.2.18, we know that  $P(X_1 = 2, X_2 = 2) = \frac{6!}{2!2!2!} (0.25)^2 (0.50)^2 (0.25)^2 = 0.088$ . The simplest way to deal with the marginal probability is to recognize that the probability of belonging to the middle half is binomial with  $n = 6$  and  $p = .05$ . This probability is  $\binom{6}{2} (0.5)^2 (0.5)^4 = 0.234$ .

$$\mathbf{3.7.19} \quad (\text{a}) \quad f_X(x) = \int_0^1 \frac{1}{2} dy = \frac{y}{2} \Big|_0^1 = \frac{1}{2}, 0 \leq x \leq 2$$

$$f_Y(y) = \int_0^2 \frac{1}{2} dx = \frac{x}{2} \Big|_0^2 = 1, 0 \leq y \leq 1$$

$$(\text{b}) \quad f_X(x) = \int_0^1 \frac{3}{2} y^2 dy = \frac{1}{2} y^3 \Big|_0^1 = 1/2, 0 \leq x \leq 2$$

$$f_Y(y) = \int_0^2 \frac{3}{2} y^2 dx = \frac{3}{2} y^2 x \Big|_0^2 = 3y^2, 0 \leq y \leq 1$$

$$(\text{c}) \quad f_X(x) = \int_0^1 \frac{2}{3} (x+2y) dy = \frac{2}{3} (xy + y^2) \Big|_0^1 = \frac{2}{3} (x+1), 0 \leq x \leq 1$$

$$f_Y(y) = \int_0^1 \frac{2}{3} (x+2y) dx = \frac{2}{3} \left( \frac{x^2}{2} + 2xy \right) \Big|_0^1 = \frac{4}{3} y + \frac{1}{3}, 0 \leq y \leq 1$$

$$(d) f_X(x) = c \int_0^1 (x+y) dy = c \left( xy + \frac{y^2}{2} \right) \Big|_0^1 = c \left( x + \frac{1}{2} \right), 0 \leq x \leq 1$$

In order for the above to be a density,  $1 = \int_0^1 c \left( x + \frac{1}{2} \right) dx = c \left( \frac{x^2}{2} + \frac{x}{2} \right) \Big|_0^1 = c$ , so

$$f_X(x) = x + \frac{1}{2}, 0 \leq x \leq 1$$

$$f_Y(y) = y + \frac{1}{2}, 0 \leq y \leq 1, \text{ by symmetry of the joint pdf}$$

$$(e) f_X(x) = \int_0^1 4xy dy = 2xy^2 \Big|_0^1 = 2x, 0 \leq x \leq 1$$

$$f_Y(y) = 2y, 0 \leq y \leq 1, \text{ by the symmetry of the joint pdf}$$

$$(f) f_X(x) = \int_0^\infty xye^{-(x+y)} dy = xe^{-x} \int_0^\infty ye^{-y} dy = xe^{-x} (-ye^{-y} - e^{-y}) \Big|_0^\infty = xe^{-x}, 0 \leq x$$

$$f_Y(y) = ye^{-y}, 0 \leq y, \text{ by symmetry of the joint pdf}$$

$$(g) f_X(x) = \int_0^\infty ye^{-xy-y} dy = \int_0^\infty ye^{-(x+1)y} dy$$

$$\text{Integrating by parts gives } \left( -\frac{y}{x+1} e^{-(x+1)y} - \left( \frac{1}{x+1} \right)^2 e^{-(x+1)y} \right) \Big|_0^\infty = \left( \frac{1}{x+1} \right)^2, 0 < x$$

$$f_Y(y) = \int_0^\infty ye^{-xy-y} dx = \int_0^\infty ye^{-y} e^{-xy} dx = ye^{-y} \left( -\frac{1}{y} \right) e^{-xy} \Big|_0^\infty = e^{-y}, \text{ where } 0 \leq y.$$

$$3.7.20 \quad (a) f_X(x) = \int_x^2 \frac{1}{2} dy = \frac{y}{2} \Big|_x^2 = 1 - \frac{x}{2}, 0 \leq x \leq 2; f_Y(y) = \int_0^y \frac{1}{2} dx = \frac{1}{2} y, 0 \leq y \leq 2$$

$$(b) f_X(x) = \int_{-\infty}^\infty f_{X,Y}(x,y) dy = \int_0^x \frac{1}{x} dy = \frac{1}{x} y \Big|_0^x = 1, 0 \leq x \leq 1$$

$$f_Y(y) = \int_{-\infty}^\infty f_{X,Y}(x,y) dx = \int_y^1 \frac{1}{x} dx = \ln x \Big|_y^1 = -\ln y, 0 \leq y \leq 1$$

$$(c) f_X(x) = \int_{-\infty}^\infty f_{X,Y}(x,y) dy = \int_0^{1-x} 6x dy = 6xy \Big|_0^{1-x} = 6x(1-x), 0 \leq x \leq 1$$

$$f_Y(y) = \int_{-\infty}^\infty f_{X,Y}(x,y) dx = \int_0^{1-y} 6x dx = 3x^2 \Big|_0^{1-y} = 3(1-y)^2, 0 \leq y \leq 1$$

$$\begin{aligned}
 3.7.21 \quad f_X(x) &= \int_0^{1-x} 6(1-x-y)dy = 6 \left( y - xy - \frac{y^2}{2} \right) \Big|_0^{1-x} = 6 \left[ (1-x) - x(1-x) - \frac{(1-x)^2}{2} \right] \\
 &= 3 - 6x + 3x^2, 0 \leq x \leq 1
 \end{aligned}$$

$$3.7.22 \quad f_Y(y) = \int_0^y 2e^{-x}e^{-y}dx = -2e^{-x}e^{-y} \Big|_0^y = 2e^{-y} - 2e^{-2y}, 0 \leq y$$

$$\begin{aligned}
 3.7.23 \quad p_X(x) &= \sum_{y=0}^{4-x} \frac{4!}{x!y!(4-x-y)!} \left(\frac{1}{2}\right)^x \left(\frac{1}{3}\right)^y \left(\frac{1}{6}\right)^{4-x-y} \\
 &= \frac{4!}{x!(4-x)!} \left(\frac{1}{2}\right)^x \sum_{y=0}^{4-x} \frac{(4-x)!}{y![(4-x)-y]!} \left(\frac{1}{3}\right)^y \left(\frac{1}{6}\right)^{4-x-y} = \frac{4!}{x!(4-x)!} \left(\frac{1}{2}\right)^x \left(\frac{1}{3} + \frac{1}{6}\right)^{4-x} \\
 &= \binom{4}{x} \left(\frac{1}{2}\right)^x \left(\frac{1}{2}\right)^{4-x}
 \end{aligned}$$

Thus,  $X$  is binomial with  $n = 4$  and  $p = 1/2$ . Similarly,  $Y$  is binomial with  $n = 4$  and  $p = 1/3$ .

3.7.24 (a) Consider any outcome with  $x$  of the first kind,  $y$  of the second, and (necessarily)  $n - x - y$  of the third kind. The probability of such an outcome is  $p_1^x p_2^y (1 - p_1 - p_2)^{n-x-y}$ . All we need to know now is how many outcomes there are with  $x$  of the first kind,  $y$  of the second, and  $n - x - y$  of the third kind. This question is resolved by the number of ways to choose the places for these three kinds of outcomes, which by Theorem 2.6.2 is  $\frac{n!}{x!y!(n-x-y)!}$ .

(b) The proof is an adaptation of the solution to Question 3.7.23.

3.7.25 (a)  $S = \{(H, 1), (H, 2), (H, 3), (H, 4), (H, 5), (H, 6), (T, 1), (T, 2), (T, 3), (T, 4), (T, 5), (T, 6)\}$   
 (b)  $F_{X,Y}(1, 2) = P(X \leq 1, Y \leq 2) = P(\{(H, 1), (H, 2), (T, 1), (T, 2)\}) = 4/12 = 1/3$

$$\begin{aligned}
3.7.26 \quad F_{X,Y}(1, 2) &= \sum_{i=0}^1 \sum_{j=0}^2 p_{X,Y}(i, j) \\
&= \frac{\binom{5}{0} \binom{4}{1} \binom{3}{3}}{\binom{12}{4}} + \frac{\binom{5}{0} \binom{4}{2} \binom{3}{2}}{\binom{12}{4}} + \frac{\binom{5}{1} \binom{4}{0} \binom{3}{3}}{\binom{12}{4}} + \frac{\binom{5}{1} \binom{4}{1} \binom{3}{2}}{\binom{12}{4}} + \frac{\binom{5}{1} \binom{4}{2} \binom{3}{1}}{\binom{12}{4}} \\
&= \frac{4 + 18 + 5 + 60 + 90}{495} = \frac{177}{495} = 0.358
\end{aligned}$$

$$3.7.27 \quad (a) \quad F_{X,Y}(u, v) = \int_0^u \int_0^v \frac{3}{2} y^2 dy dx = \int_0^u \left[ \frac{1}{2} y^3 \right]_0^v dx = \int_0^u \frac{1}{2} v^3 dx = \frac{1}{2} uv^3$$

$$(b) \quad F_{X,Y}(u, v) = \int_0^u \int_0^v \frac{2}{3} (x + 2y) dy dx = \int_0^u \left[ \frac{2}{3} (xy + y^2) \right]_0^v dx = \int_0^u \frac{2}{3} (vx + v^2) dx = \frac{1}{3} u^2 v + \frac{2}{3} uv^2$$

$$(c) \quad F_{X,Y}(u, v) = \int_0^u \int_0^v 4xy dy dx = \int_0^u x \left[ 2y^2 \right]_0^v dx = 2v^2 \int_0^u x dx = u^2 v^2$$

$$3.7.28 \quad (a) \quad F_{X,Y}(u, v) = \int_0^u \int_x^v \frac{1}{2} dy dx = \int_0^u \left[ \frac{1}{2} y \right]_x^v dx = \int_0^u \frac{1}{2} (v - x) dx = \frac{1}{4} (2uv - u^2)$$

$$(b) \quad F_{X,Y}(u, v) = \int_0^v \int_y^u \frac{1}{x} dy dx = \int_0^v \left[ \ln x \right]_y^u dy = \int_0^v \ln u - \ln y dy = v \ln u - v \ln v + v$$

(c) Case I:  $v \leq 1 - u$

$$F_{X,Y}(u, v) = \int_0^v \int_0^u 6x dx dy = \int_0^v \left[ 3x^2 \right]_0^u dy = \int_0^v 3u^2 dy = 3u^2 v$$

Case II:  $v > 1 - u$

$$\begin{aligned}
F_{X,Y}(u, v) &= \int_0^u \int_0^v 6x dy dx = \int_{1-v}^u \int_{1-x}^v 6x dy dx \\
&= 3u^2 v - [3u^2 v - 3u^2 + 2u^3 - 3(1-v)^2 v + 3(1-v)^2 - 2(1-v)^3] \\
&= 3u^2 - 2u^3 + 3(1-v)^2 v - 3(1-v)^2 + 2(1-v)^3 = 3u^2 - 2u^3 - (1-v)^3
\end{aligned}$$

**3.7.29** By Theorem 3.7.3,  $f_{X,Y} = \frac{\partial^2}{\partial x \partial y} F_{X,Y} = \frac{\partial^2}{\partial x \partial y} (xy) = \frac{\partial}{\partial x} \left( \frac{\partial}{\partial y} xy \right) = \frac{\partial}{\partial x} (x) = 1, 0 \leq x \leq 1, 0 \leq y \leq 1.$

The graph of  $f_{X,Y}$  is a plane of height one over the unit square.

**3.7.30** By Theorem, 3.7.3,  $f_{X,Y} = \frac{\partial^2}{\partial x \partial y} F_{X,Y} = \frac{\partial^2}{\partial x \partial y} [(1 - e^{-\lambda y})(1 - e^{-\lambda x})]$

$$= \frac{\partial}{\partial x} \frac{\partial}{\partial y} [(1 - e^{-\lambda y})(1 - e^{-\lambda x})] = \frac{\partial}{\partial x} [(\lambda e^{-\lambda y})(1 - e^{-\lambda x})] = \lambda e^{-\lambda y} \lambda e^{-\lambda x}, x \geq 0, y \geq 0$$

**3.7.31** First note that  $1 = F_{X,Y}(1, 1) = k[4(1^2)(1^2) + 5(1)(1^4)] = 9k$ , so  $k = 1/9$ .

Then  $f_{X,Y} = \frac{\partial^2}{\partial x \partial y} F_{X,Y} = \frac{\partial^2}{\partial x \partial y} \left( \frac{4}{9} x^2 y^2 + \frac{5}{9} xy^4 \right)$

$$= \frac{\partial}{\partial x} \frac{\partial}{\partial y} \left( \frac{4}{9} x^2 y^2 + \frac{5}{9} xy^4 \right) = \frac{\partial}{\partial x} \left( \frac{8}{9} x^2 y + \frac{20}{9} xy^3 \right) = \frac{16}{9} xy + \frac{20}{9} y^3$$

$$P(0 < X < 1/2, 1/2 < Y < 1) = \int_0^{1/2} \int_{1/2}^1 \left( \frac{16}{9} xy + \frac{20}{9} y^3 \right) dy dx$$

$$= \int_0^{1/2} \left. \frac{8}{9} xy^2 + \frac{5}{9} y^4 \right|_{1/2}^1 dx = \int_0^{1/2} \left( \frac{2}{3} x + \frac{25}{48} \right) dx = \left. \frac{1}{3} x^2 + \frac{25}{48} x \right|_0^{1/2} = 11/32$$

**3.7.32**  $P(a < X \leq b, Y \leq d) = F_{X,Y}(b, d) - F_{X,Y}(a, d)$

$$P(a < X \leq b, Y \leq c) = F_{X,Y}(b, c) - F_{X,Y}(a, c)$$

$$P(a < X \leq b, c < Y \leq d) = P(a < X \leq b, Y \leq d) - P(a < X \leq b, Y \leq c)$$

$$= (F_{X,Y}(b, d) - F_{X,Y}(a, d)) - (F_{X,Y}(b, c) - F_{X,Y}(a, c))$$

$$= F_{X,Y}(b, d) - F_{X,Y}(a, d) - F_{X,Y}(b, c) + F_{X,Y}(a, c)$$

**3.7.33**  $P(X_1 \geq 1050, X_2 \geq 1050, X_3 \geq 1050, X_4 \geq 1050)$

$$= \int_{1050}^{\infty} \int_{1050}^{\infty} \int_{1050}^{\infty} \int_{1050}^{\infty} \prod_{i=1}^4 \frac{1}{1000} e^{-x_i/1000} dx_1 dx_2 dx_3 dx_4 = \left( \int_{1050}^{\infty} \frac{1}{1000} e^{-x/1000} dx \right)^4 = (e^{-1.05})^4 = 0.015$$

$$3.7.34 \quad (a) \quad p_{X,Y,Z}(x, y, z) = \frac{\binom{4}{x} \binom{4}{y} \binom{4}{z} \binom{40}{6-x-y-z}}{\binom{52}{6}} \quad \text{where } 0 \leq x, y, z \leq 4, x+y+z \leq 6$$

$$(b) \quad p_{X,Y}(x, y) = \frac{\binom{4}{x} \binom{4}{y} \binom{44}{6-x-y}}{\binom{52}{6}} \quad \text{where } 0 \leq x, y \leq 4, x+y \leq 6$$

$$p_{X,Z}(x, z) = \frac{\binom{4}{x} \binom{4}{z} \binom{44}{6-x-z}}{\binom{52}{6}} \quad \text{where } 0 \leq x, z \leq 4, x+z \leq 6$$

$$3.7.35 \quad p_{X,Y}(0, 1) = \sum_{z=0}^2 p_{X,Y,Z}(0, 1, z) = \frac{3!}{0!1!} \left(\frac{1}{2}\right)^0 \left(\frac{1}{12}\right)^1 \sum_{z=0}^2 \frac{1}{z!(2-z)!} \left(\frac{1}{6}\right)^z \left(\frac{1}{4}\right)^{2-z}$$

$$= \frac{3!}{0!1!} \left(\frac{1}{2}\right)^0 \left(\frac{1}{12}\right)^1 \left(\frac{1}{2}\right) \sum_{z=0}^2 \frac{2!}{z!(2-z)!} \left(\frac{1}{6}\right)^z \left(\frac{1}{4}\right)^{2-z} = \frac{3!}{0!1!} \left(\frac{1}{2}\right)^0 \left(\frac{1}{12}\right)^1 \left(\frac{1}{2}\right) \left(\frac{1}{6} + \frac{1}{4}\right)^2 = \frac{25}{576}$$

$$3.7.36 \quad (a) \quad f_{X,Y}(x, y) = \int_0^\infty f_{X,Y,Z}(x, y, z) dz = \int_0^\infty (x+y)e^{-z} dz$$

$$= (x+y) \left[ -e^{-z} \right]_0^\infty = (x+y), \quad 0 \leq x, y \leq 1$$

$$(b) \quad f_{Y,Z}(y, z) = \int_0^1 f_{X,Y,Z}(x, y, z) dx = \int_0^1 (x+y)e^{-z} dx = e^{-z} \left[ \frac{x^2}{2} + xy \right]_0^1 = \left( \frac{1}{2} + y \right) e^{-z},$$

$$0 \leq y \leq 1, z \geq 0$$

$$(c) \quad f_Z(z) = \int_0^1 f_{Y,Z}(y, z) dy = \int_0^1 \left( \frac{1}{2} + y \right) e^{-z} dy = e^{-z} \left[ \frac{y}{2} + \frac{y^2}{2} \right]_0^1 = e^{-z}, \quad z \geq 0$$

$$3.7.37 \quad f_{W,X}(w, x) = \int_0^1 \int_0^1 f_{W,X,Y,Z}(w, x, y, z) dy dz = \int_0^1 \int_0^1 16wxyz \, dy dz = \int_0^1 \left[ 8wxy^2 z \right]_0^1 dz = \int_0^1 [8wxz] dz$$

$$= \left[ 4wxz^2 \right]_0^1 = 4wx, \quad 0 < w, x < 1$$

$$P(0 < W < 1/2, 1/2 < X < 1) = \int_0^{1/2} \int_{1/2}^1 4wx \, dx \, dw$$

$$= \int_0^{1/2} 2w \left[ x^2 \right]_{1/2}^1 dx = \int_0^{1/2} \frac{3}{2} w \, dw = \frac{3}{4} w^2 \Big|_0^{1/2} = \frac{3}{16}$$

**3.7.38** We must show that  $p_{X,Y}(j, k) = p_X(j)p_Y(k)$ . But for any pair  $(j, k)$ ,  $p_{X,Y}(j, k) = 1/36 = (1/6)(1/6) = p_X(j)p_Y(k)$ .

**3.7.39** The marginal pdfs for  $f_{X,Y}$  are  $f_X(x) = \lambda e^{-\lambda x}$  and  $f_Y(y) = \lambda e^{-\lambda y}$  (Hint: see the solution to 3.7.19(f)). Their product is  $f_{X,Y}$ , so  $X$  and  $Y$  are independent. The probability that one component fails to last 1000 hours is  $1 - e^{-1000\lambda}$ . Because of independence of the two components, the probability that two components both fail is the square of that, or  $(1 - e^{-1000\lambda})^2$ .

**3.7.40** (a) 
$$p_{X,Y}(x, y) = \begin{cases} \frac{1}{4} \cdot \frac{2}{5} = \frac{1}{10} & y = x \\ \frac{1}{4} \cdot \frac{1}{5} = \frac{1}{20} & y \neq x \end{cases}$$

(b)  $p_X(x) = 1/4$ , since each ball in Urn I is equally likely to be drawn

$$p_Y(y) = 1/10 + 3(1/20) = 1/4$$

(c)  $P(X = 1, Y = 1) = 1/10$ , but  $P(X = 1)P(Y = 1) = 1/16$

**3.7.41** First, note  $k = 2$ . Then, 2 times area of  $A = P(Y \geq 3/4)$ . Also, 2 times area of  $B = P(X \geq 3/4)$ . The square  $C$  is the set  $(X \geq 3/4) \cap (Y \geq 3/4)$ . However,  $C$  is in the region where the density is 0. Thus,  $P((X \geq 3/4) \cap (Y \geq 3/4))$  is zero, but the product  $P(X \geq 3/4)P(Y \geq 3/4)$  is not zero.

$$3.7.42 \quad f_X(x) = \int_0^1 \frac{2}{3}(x+2y)dy = \frac{2}{3}(x+1)$$

$$f_Y(y) = \int_0^1 \frac{2}{3}(x+2y)dx = \frac{2}{3}\left(2y + \frac{1}{2}\right)$$

$$\text{But } \frac{2}{3}(x+1)\frac{2}{3}\left(2y + \frac{1}{2}\right) \neq \frac{2}{3}(x+2y).$$

$$3.7.43 \quad P(Y < X) = \int_0^1 \int_0^x f_{X,Y}(x,y) dy dx = \int_0^1 \int_0^x (2x)(3y^2) dy dx = \int_0^1 2x^4 dx = \frac{2}{5}$$

$$3.7.44 \quad F_X(x) = \int_0^x \frac{t}{2} dt = \frac{x^2}{4}. \quad F_Y(y) = \int_0^y 2t dt = y^2$$

$$F_{X,Y}(x,y) = F_X(x)F_Y(y) = \frac{x^2 y^2}{4}, \quad 0 \leq x \leq 2, \quad 0 \leq y \leq 1$$

$$3.7.45 \quad P\left(\frac{Y}{X} > 2\right) = P(Y > 2X) = \int_0^1 \int_0^{y/2} (2x)(1) dx dy = \int_0^1 \left[x^2\right]_0^{y/2} dy = \frac{y^3}{12} \Big|_0^1 = \frac{1}{12}$$

$$3.7.46 \quad P(a < X < b, c < Y < d) = \int_a^b \int_c^d xye^{-(x+y)} dy dx = \int_a^b xe^{-x} \left( \int_c^d ye^{-y} dy \right) dx = \int_a^b xe^{-x} dx \int_c^d ye^{-y} dy$$

$$= P(a < X < b) P(c < Y < d)$$

$$3.7.47 \quad \text{Take } a = c = 0, b = d = 1/2. \text{ Then } P(0 < X < 1/2, 0 < Y < 1/2) = \int_0^{1/2} \int_0^{1/2} (2x + y - 2xy) dy dx$$

$$= 5/32.$$

$$f_X(x) = \int_0^1 (2x + y - 2xy) dy = x + 1/2, \text{ so } P(0 < X < 1/2) = \int_0^{1/2} \left(x + \frac{1}{2}\right) dx = \frac{3}{8}$$

$$f_Y(y) = \int_0^1 (2x + y - 2xy) dx = 1, \text{ so } P(0 < Y < 1/2) = 1/2. \text{ But, } 5/32 \neq (3/8)(1/2)$$

3.7.48 We proceed by showing that the events  $g(X) \in A$  and  $h(Y) \in B$  are independent, for sets of real numbers,  $A$  and  $B$ . Note that  $P(g(X) \in A \text{ and } h(Y) \in B) = P(X \in g^{-1}(A) \text{ and } Y \in h^{-1}(B))$ .

Since  $X$  and  $Y$  are independent,  $P(X \in g^{-1}(A) \text{ and } Y \in g^{-1}(B)) = P(X \in g^{-1}(A))P(Y \in g^{-1}(B)) = P(g(X) \in A)P(h(Y) \in B)$

**3.7.49** Let  $K$  be the region of the plane where  $f_{X,Y} \neq 0$ . If  $K$  is not a rectangle with sides parallel to the coordinate axes, there exists a rectangle  $A = \{(x, y) | a \leq x \leq b, c \leq y \leq d\}$  with  $A \cap K = \emptyset$ , but for  $A_1 = \{(x, y) | a \leq x \leq b, \text{ all } y\}$  and  $A_2 = \{(x, y) | \text{ all } x, c \leq y \leq d\}$ ,  $A_1 \cap K \neq \emptyset$  and  $A_2 \cap K \neq \emptyset$ . Then  $P(A) = 0$ , but  $P(A_1) \neq 0$  and  $P(A_2) \neq 0$ . However,  $A = A_1 \cap A_2$ , so  $P(A_1 \cap A_2) \neq P(A_1)P(A_2)$ .

**3.7.50** 
$$f_{X_1, X_2, \dots, X_n}(x_1, x_2, \dots, x_n) = \prod_{j=1}^n (1/\lambda) e^{-x_j/\lambda} = (1/\lambda)^n e^{-\frac{1}{\lambda} \sum_{j=1}^n x_j}$$

**3.7.51** (a)  $P(X_1 < 1/2) = \int_0^{1/2} 4x^3 dx = x^4 \Big|_0^{1/2} = 1/16$

(b) This asks for the probability of exactly one success in a binomial experiment with  $n = 4$  and

$$p = 1/16, \text{ so the probability is } \binom{4}{1} (1/16)^1 (15/16)^3 = 0.206.$$

(c)  $f_{X_1, X_2, X_3, X_4}(x_1, x_2, x_3, x_4) = \prod_{j=1}^4 4x_j^3 = 256(x_1 x_2 x_3 x_4)^3, 0 \leq x_1, x_2, x_3, x_4 \leq 1$

(d)  $F_{X_2, X_3}(x_2, x_3) = \int_0^{x_3} \int_0^{x_2} (4s^3)(4t^3) ds dt = \int_0^{x_2} 4s^2 ds \int_0^{x_3} 4t^3 dt = x_2^4 x_3^4, 0 \leq x_2, x_3 \leq 1.$

**3.7.52**  $P(X_1 < 1/2, X_2 > 1/2, X_3 < 1/2, X_4 > 1/2, \dots, X_{2k} > 1/2)$   
 $= P(X_1 < 1/2)P(X_2 > 1/2)P(X_3 < 1/2)P(X_4 > 1/2), \dots, P(X_{2k} > 1/2)$  because the  $X_i$  are independent. Since the  $X_i$  are uniform over the unit interval,  $P(X_i < 1/2) = P(X_i > 1/2) = 1/2$ . Thus the desired probability is  $(1/2)^{2k}$ .

## Section 3.8: Transforming and Combining Random Variables

**3.8.1** By Theorem 3.8.2  $f_W(w) = \frac{1}{|-4|} \cdot \frac{1}{2} \left( 1 + \frac{w-7}{-4} \right) = \frac{1}{32} (11-w)$

$-1 \leq y \leq 1$  implies  $4 \geq -4y \geq -4$  or  $3 \leq -4y + 7 \leq 11$ , so  $3 \leq w \leq 11$

**3.8.2** By Theorem 3.8.2  $f_w(w) = \frac{1}{|3|} \cdot \frac{3}{14} \left[ 1 + \left( \frac{w-2}{3} \right)^2 \right] = \frac{1}{126} (w^2 - 4w + 13)$

$0 \leq y \leq 2$  implies  $0 \leq 3y \leq 6$  or  $2 \leq 3y + 2 \leq 8$ , so  $2 \leq w \leq 8$

**3.8.3** (a)  $p_{X+Y}(w) = \sum_{\text{all } x} p_X(x) p_Y(w-x)$ . Since  $p_X(x) = 0$  for negative  $x$ , we can take the lower limit

of the sum to be 0. Since  $p_Y(w-x) = 0$  for  $w-x < 0$ , or  $x > w$ , we can take the upper limit of the sum to be  $w$ . Then we obtain

$$\begin{aligned} p_{X+Y}(w) &= \sum_{k=0}^w e^{-\lambda} \frac{\lambda^k}{k!} e^{-\mu} \frac{\mu^{w-k}}{(w-k)!} = e^{-(\lambda+\mu)} \sum_{k=0}^w \frac{1}{k!(w-k)!} \lambda^k \mu^{w-k} \\ &= e^{-(\lambda+\mu)} \frac{1}{w!} \sum_{k=0}^w \frac{w!}{k!(w-k)!} \lambda^k \mu^{w-k} = e^{-(\lambda+\mu)} \frac{1}{w!} (\lambda + \mu)^w, \quad w = 0, 1, 2, \dots \end{aligned}$$

This pdf has the same form as the ones for  $X$  and  $Y$ , but with parameter  $\lambda + \mu$

(b)  $p_{X+Y}(w) = \sum_{\text{all } x} p_X(x) p_Y(w-x)$ . The lower limit of the sum is 1. For this pdf, we must have

$w - k \geq 1$  so the upper limit of the sum is  $w - 1$ .

$$\text{Then } p_{X+Y}(w) = \sum_{k=1}^{w-1} (1-p)^{k-1} p (1-p)^{w-k-1} p = (1-p)^{w-2} p^2 \sum_{k=1}^{w-1} 1 = (w-1)(1-p)^{w-2} p^2,$$

$w = 2, 3, 4, \dots$  The pdf for  $X + Y$  does not have the same form as those for  $X$  and  $Y$ , but

Section 4.5 will show that they all belong to the same family—the negative binomial.

**3.8.4**  $f_{X+Y}(w) = \int_{-\infty}^{\infty} f_X(x) f_Y(w-x) dx = \int_0^w (x e^{-x}) (e^{-(w-x)}) dx = e^{-w} \int_0^w x dx = \frac{w^2}{2} e^{-w}, \quad w \geq 0$

**3.8.5** First suppose that  $0 \leq w \leq 1$ . As in the previous problem the upper limit of the integral is  $w$ , and

$$f_{X+Y}(w) = \int_0^w (1)(1) dx = w. \text{ Now consider the case } 1 \leq w \leq 2. \text{ Here, the first integrand vanishes}$$

unless  $x \leq 1$ . Also, the second pdf is 0 unless  $w - x \leq 1$  or  $x \geq w - 1$ .

$$\text{Then } f_{X+Y}(w) = \int_{w-1}^1 (1)(1) dx = 2 - w.$$

In summary,  $f_{X+Y}(w) = \begin{cases} w & 0 \leq w \leq 1 \\ 2-w & 1 \leq w \leq 2 \end{cases}$

**3.8.6** Consider the continuous case. It suffices to show that

$$F_{V, X+Y} = F_V F_{X+Y}. \quad F_{V, X+Y}(v, w) = P(V \leq v, X + Y \leq w) = \\ \int_{-\infty}^v \int_{-\infty}^{\infty} \int_{-\infty}^{w-x} f_V(v) f_X(x) f_Y(y) dy dx dv = \int_{-\infty}^v f_V(v) \left( \int_{-\infty}^{\infty} \int_{-\infty}^{w-x} f_X(x) f_Y(y) dy dx \right) dv = F_V(v) F_{X+Y}(w)$$

**3.8.7**  $F_W(w) = P(W \leq w) = P(Y^2 \leq w) = P(Y \leq \sqrt{w}) = f = F_Y(\sqrt{w})$

Now differentiate both sides to obtain  $f_W(w) = \frac{d}{dw} F_W(w) = \frac{d}{dw} F_Y(\sqrt{w}) = \frac{1}{2\sqrt{w}} f_Y(\sqrt{w})$ .

**3.8.8** From Question 3.8.7,  $f_W(w) = \frac{1}{2\sqrt{w}} f_Y(\sqrt{w})$ . Since  $f_Y(\sqrt{w}) = 1$ ,  $f_W(w) = \frac{1}{2\sqrt{w}}$ ,  $0 \leq w \leq 1$ .

**3.8.9** From Question 3.8.7,  $f_W(w) = \frac{1}{2\sqrt{w}} f_Y(\sqrt{w})$ .

Thus  $f_W(w) = \frac{1}{2\sqrt{w}} 6\sqrt{w}(1-\sqrt{w}) = 3(1-\sqrt{w})$  where  $0 \leq w \leq 1$ .

**3.8.10** From Question 3.8.7

$$f_{Y^2}(u) = \frac{1}{2\sqrt{u}} f_Y(\sqrt{u}) = \frac{1}{2\sqrt{u}} a(\sqrt{u})^2 e^{-b(\sqrt{u})^2} = \frac{1}{2} a\sqrt{u} e^{-bu}.$$

Then  $f_W(w) = \frac{2}{m} f_u\left(\frac{2}{m}w\right) = \frac{2}{m} \frac{1}{2} a\sqrt{\frac{2}{m}w} e^{-b(2w/m)} = \frac{\sqrt{2}}{m^{3/2}} a\sqrt{w} e^{-b(2w/m)}$ ,  $0 \leq w$ .

**3.8.11** (a) Let  $W = XY$ . Then  $f_W(w) = \int_{-\infty}^{\infty} \frac{1}{|x|} f_X(x) f_Y(w/x) dx$

Since  $f_Y(w/x) \neq 0$  when  $0 \leq w/x \leq 1$ , then we need only consider  $w \leq x$ . Similarly,  $f_X(x) \neq 0$

implies  $x \leq 1$ . Thus the integral becomes  $\int_w^1 \frac{1}{x} dx = \ln x \Big|_w^1 = -\ln w$ ,  $0 \leq w \leq 1$ .

(b) Again let  $W = XY$ . Since the range of integration here is the same as in Part (a), we can write

$$f_W(w) = \int_{-\infty}^{\infty} \frac{1}{|x|} f_X(x) f_Y(w/x) dx = \int_w^1 \frac{1}{x} 2(x) 2(w/x) dx = 4w \int_w^1 \frac{1}{x} dx = -4w \ln w, \quad 0 \leq w \leq 1.$$

**3.8.12** (a) Let  $W = Y/X$ . Then  $f_W(w) = \int_{-\infty}^{\infty} |x| f_X(x) f_Y(wx) dx$

Since  $f_X(x) = 0$  for  $x < 0$ , the lower limit of the integral is 0. Since  $f_Y(wx) = 0$  for  $wx > 1$ , we must have  $wx \leq 1$  or  $x \leq 1/w$ .

Case I:  $0 \leq w \leq 1$ : In this case  $1/w > 1$ , so the upper limit of the integral is 1.

$$f_W(w) = \int_{-\infty}^{\infty} |x| f_X(x) f_Y(xw) dx = \int_0^1 x(1)(1) dx = 1/2$$

Case II:  $w > 1$ : In this case  $1/w \leq 1$ , so the upper limit of the integral is  $1/w$ .

$$f_W(w) = \int_{-\infty}^{\infty} |x| f_X(x) f_Y(xw) dx = \int_0^{1/w} x(1)(1) dx = \frac{1}{2w^2}$$

(b) Case I:  $0 \leq w \leq 1$ : The limits of the integral are 0 and 1.

$$f_W(w) = \int_{-\infty}^{\infty} |x| f_X(x) f_Y(xw) dx = \int_0^1 x(2x)(2wx) dx = w$$

Case II:  $w > 1$ : The limits of the integral are 0 and  $1/w$ .

$$f_W(w) = \int_{-\infty}^{\infty} |x| f_X(x) f_Y(xw) dx = \int_0^{1/w} x(2x)(2xw) dx = \frac{1}{w^3}$$

**3.8.13** Let  $W = Y/X$ . Then  $f_W(w) = \int_{-\infty}^{\infty} |x| f_X(x) f_Y(wx) dx = \int_0^{\infty} x(xe^{-x})e^{-wx} dx = \int_0^{\infty} x^2 e^{-(1+w)x} dx$

$$= \frac{1}{1+w} \left( \int_0^{\infty} x^2 (1+w) e^{-(1+w)x} dx \right)$$

Let  $V$  be the exponential random variable with parameter  $1+w$ . Then the quantity in parentheses above is  $E(V^2)$ .

$$\text{But } E(V)^2 = \text{Var}(V) + E(V^2) = \frac{1}{(1+w)^2} + \frac{1}{(1+w)^2} = \frac{2}{(1+w)^2} \quad (\text{See Question 3.6.11}).$$

$$\text{Thus, } f_W(w) = \frac{1}{1+w} \left( \frac{2}{(1+w)^2} \right) = \frac{2}{(1+w)^3}, \quad 0 \leq w.$$

## Section 3.9: Further Properties of the Mean and Variance

**3.9.1** Let  $X_i$  be the number from the  $i$ -th draw,  $i = 1, \dots, r$ . Then for each  $i$ ,  $\frac{1+2+\dots+n}{n} = \frac{n+1}{2}$

$E(X_i) = \frac{1+2+\dots+n}{n} = \frac{n+1}{2}$ . The sum of the numbers drawn is  $\sum_{i=1}^r X_i$ , so the expected value of

the sum is  $\sum_{i=1}^r E(X_i) = \frac{r(n+1)}{2}$ .

**3.9.2**  $f_{X,Y}(x, y) = \lambda^2 e^{-\lambda(x+y)} = (\lambda e^{-\lambda x})(\lambda e^{-\lambda y})$  implies that  $f_X(x) = \lambda e^{-\lambda x}$  and  $f_Y(y) = \lambda e^{-\lambda y}$ .

Then  $E(X + Y) = E(X) + E(Y) = \frac{1}{\lambda} + \frac{1}{\lambda} = \frac{2}{\lambda}$

**3.9.3** From Question 3.7.19(c),  $f_X(x) = \frac{2}{3}(x+1)$ ,  $0 \leq x \leq 1$ , so  $E(X) = \int_0^1 x \frac{2}{3}(x+1) dx$

$$= \frac{2}{3} \int_0^1 (x^2 + x) dx = \frac{5}{9}$$

Also,  $f_Y(y) = \frac{4}{3}y + \frac{1}{3}$ ,  $0 \leq y \leq 1$ , so  $E(Y) = \int_0^1 y \left( \frac{4}{3}y + \frac{1}{3} \right) dy = \int_0^1 \left( \frac{4}{3}y^2 + \frac{1}{3}y \right) dy = \frac{11}{8}$ .

Then  $E(X + Y) = E(X) + E(Y) = \frac{5}{9} + \frac{11}{8} = \frac{7}{6}$ .

**3.9.4** Let  $X_i = 1$  if a shot with the first gun is a bull's eye and 0 otherwise,  $i = 1, \dots, 10$ .  $E(X_i) = 0.30$ .

Let  $V_i = 1$  if a shot with the second gun is a bull's-eye and 0 otherwise,  $i = 1, \dots, 10$ .

$E(V_i) = 0.40$ .

Cathie's score is  $4 \sum_{i=1}^{10} X_i + 6 \sum_{i=1}^{10} V_i$ , and her expected score is  $E \left( 4 \sum_{i=1}^{10} X_i + 6 \sum_{i=1}^{10} V_i \right)$

$$= 4 \sum_{i=1}^{10} E(X_i) + 6 \sum_{i=1}^{10} E(V_i) = 4(10)(0.30) + 6(10)(0.40) = 36.$$

**3.9.5**  $\mu = E\left(\sum_{i=1}^n a_i X_i\right) = \sum_{i=1}^n a_i E(X_i) = \sum_{i=1}^n a_i \mu = \mu \sum_{i=1}^n a_i$ , so the given equality occurs if and only if

$$\sum_{i=1}^n a_i = 1.$$

**3.9.6** Let  $X_i$  be the daily closing price of the stock on day  $i$ . The daily expected gain is  $E(X_i) = (1/8)p - (1/8)q = (1/8)(p - q)$ . After  $n$  days the expected gain is  $(n/8)(p - q)$ .

**3.9.7** (a)  $E(X_i)$  is the probability that the  $i$ -th ball drawn is red,  $1 \leq i \leq n$ . Draw the balls in order without replacement, but do not note the colors. Then look at the  $i$ -th ball first. The probability that it is red is surely independent of when it is drawn. Thus, all of these expected values are the same and each equals  $r/(r + w)$ .

(b) Let  $X$  be the number of red balls drawn. Then  $X = \sum_{i=1}^n X_i$  and  $E(X) = \sum_{i=1}^n E(X_i) = nr/(r + w)$ .

**3.9.8** Let  $X_1$  = number showing on face 1;  $X_2$  = number showing on face 2. Since  $X_1$  and  $X_2$  are independent,  $E(X_1 X_2) = E(X_1)E(X_2) = (3.5)(3.5) = 12.25$ .

**3.9.9** First note that  $1 = \int_{10}^{20} \int_{10}^{20} k(x + y) dy dx = k3000$ , so  $k = \frac{1}{3000}$ .

If  $\frac{1}{R} = \frac{1}{X} + \frac{1}{Y}$ , then  $R = \frac{XY}{X + Y}$ .

$$E(R) = \frac{1}{3000} \int_{10}^{20} \int_{10}^{20} \frac{xy}{x + y} (x + y) dy dx = \frac{1}{3000} \int_{10}^{20} \int_{10}^{20} xy dy dx = 7.5.$$

**3.9.10** From Question 3.8.5,  $f_{X^2}(w) = \frac{1}{2\sqrt{w}}$ , so  $E(X^2) = \int_0^1 w \frac{1}{2\sqrt{w}} dw = \frac{1}{2} \int_0^1 \sqrt{w} dw = \frac{1}{3}$ , with a similar result holding for  $Y^2$ . Then  $E(X^2 + Y^2) = 2/3$ .

**3.9.11** The area of the triangle is the random variable  $W = \frac{1}{2}XY$ .

$$\text{Then } E\left(\frac{1}{2}XY\right) = \frac{1}{2}E(XY) = \frac{1}{2}E(X)E(Y) = \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} = \frac{1}{8}$$

**3.9.12** The  $Y_i$  are independent for  $i = 1, 2, \dots, n$ .

$$\text{Thus, } E\left(\sqrt[n]{Y_1 \cdot Y_2 \cdot \dots \cdot Y_n}\right) = E\left(\sqrt[n]{Y_1}\right) \cdot E\left(\sqrt[n]{Y_2}\right) \cdot \dots \cdot E\left(\sqrt[n]{Y_n}\right)$$

The  $Y_i$  all have the same uniform pdf, so it suffices to calculate  $E\left(\sqrt[n]{Y_1}\right)$ , which is

$$\int_0^1 \sqrt[n]{y} \cdot 1 \, dy = \frac{n}{n+1}. \text{ Thus, the expected value of the geometric mean is } \left(\frac{n}{n+1}\right)^n.$$

Note that the *arithmetic* mean is constant at  $1/2$  and does not depend on the sample size.

**3.9.13**

$x$	$y$	$f_{X,Y}$	$xy$	$xyf_{X,Y}$
1	1	1/36	1	1/36
1	2	1/36	2	2/36
1	3	1/36	3	3/36
1	4	1/36	4	4/36
1	5	1/36	5	5/36
1	6	1/36	6	6/36
2	2	2/36	4	8/36
2	3	1/36	6	6/36
2	4	1/36	8	8/36
2	5	1/36	10	10/36
2	6	1/36	12	12/36
3	3	3/36	9	27/36
3	4	1/36	12	12/36
3	5	1/36	15	15/36
3	6	1/36	18	18/36
4	4	4/36	16	64/36

4	5	1/36	20	20/36
4	6	1/36	24	24/36
5	5	5/36	25	125/36
5	6	1/36	30	30/36
6	6	6/36	36	216/36

$E(XY)$  is the sum of the last column =  $\frac{616}{36}$ . Clearly  $E(X) = 7/2$ .

$$E(Y) = 1\frac{1}{36} + 2\frac{2}{36} + 3\frac{5}{36} + 4\frac{7}{36} + 5\frac{9}{36} + 6\frac{11}{36} = \frac{161}{36}$$

$$\text{Cov}(X, Y) = E(XY) - E(X)E(Y) = \frac{616}{36} - \frac{7}{2} \cdot \frac{161}{36} = \frac{105}{72}$$

**3.9.14**  $\text{Cov}(aX + b, cY + d) = E[(aX + b)(cY + d)] - E(aX + b)E(cY + d) = E(acXY + adX + bcY + bd)$   
 $- [aE(X) + b][cE(Y) + d] = acE(XY) + adE(X) + bcE(Y) + bd - acE(X)E(Y) - adE(X) - bcE(Y)$   
 $- bd = ac[E(XY) - E(X)E(Y)] = ac\text{Cov}(X, Y)$

**3.9.15**  $\int_0^{2\pi} \cos x dx = \int_0^{2\pi} \sin x dx = \int_0^{2\pi} (\cos x)(\sin x) dx = 0$ , so  $E(X) = E(Y) = E(XY) = 0$ .

Then  $\text{Cov}(X, Y) = 0$ . But  $X$  and  $Y$  are functionally dependent,  $Y = \sqrt{1 - X^2}$ , so they are probabilistically dependent.

**3.9.16**  $E(XY) = \int_0^1 y \int_{-y}^y x dx dy = \int_0^1 y \left[ \frac{x^2}{2} \right]_{-y}^y dy = \int_0^1 y \cdot 0 dy = 0$

$$E(X) = \int_0^1 \int_{-y}^y x dx dy = 0, \text{ so } \text{Cov}(X, Y) = 0. \text{ However, } X \text{ and } Y \text{ are dependent since}$$

$$P(-1/2 < x < 1/2, 0 < Y < 1/2) = P(0 < Y < 1/2) \neq P(-1/2 < x < 1/2)P(0 < Y < 1/2)$$

**3.9.17** The random variables are independent and have the same exponential pdf, so

$$\text{Var}(X + Y) = \text{Var}(X) + \text{Var}(Y). \text{ By Question 3.6.11, } \text{Var}(X) = \text{Var}(Y) = \frac{1}{\lambda^2},$$

$$\text{so } \text{Var}(X + Y) = \frac{2}{\lambda^2}.$$

**3.9.18** From Question 3.9.3, we have  $E(X + Y) = E(X) + E(Y) = 5/9 + 11/18 = 21/18 = 7/6$ .

$$\begin{aligned}
 E[(X + Y)^2] &= \int_0^1 \int_0^1 (x + y)^2 \frac{2}{3} (x + 2y) dx dy = \frac{2}{3} \int_0^1 \int_0^1 (x^2 + 2xy + y^2)(x + 2y) dx dy \\
 &= \frac{2}{3} \int_0^1 \int_0^1 (x^3 + 2x^2y + xy^2 + 2x^2y + 4xy^2 + 2y^3) dx dy \\
 &= \frac{2}{3} \int_0^1 \int_0^1 (x^3 + 4x^2y + 5xy^2 + 2y^3) dx dy = \frac{2}{3} \int_0^1 \left( \frac{1}{4}x^4 + \frac{4}{3}x^3y + \frac{5}{2}x^2y^2 + 2xy^3 \right) \Big|_0^1 dy \\
 &= \frac{2}{3} \int_0^1 \left( \frac{1}{4} + \frac{4}{3}y + \frac{5}{2}y^2 + 2y^3 \right) dy = \frac{2}{3} \left( \frac{1}{4} + \frac{4}{6} + \frac{5}{6} + \frac{2}{4} \right) = \frac{3}{2}
 \end{aligned}$$

$$\text{Then } \text{Var}(X + Y) = E[(X + Y)^2] - E(X + Y)^2 = \frac{3}{2} - \left( \frac{7}{6} \right)^2 = \frac{5}{36}.$$

**3.9.19** First note that  $f_X(x) = \frac{3}{2} \int_0^1 (x^2 + y^2) dy = \frac{3}{2} \left[ x^2y + \frac{1}{3}y^3 \right]_0^1 = \frac{3}{2}x^2 + \frac{1}{2}$

$$E(X) = \int_0^1 \left( \frac{3}{2}x^3 + \frac{1}{2}x \right) dx = \left[ \frac{3}{8}x^4 + \frac{1}{4}x^2 \right]_0^1 = \frac{5}{8}$$

$$E(X^2) = \int_0^1 \left( \frac{3}{2}x^4 + \frac{1}{2}x^2 \right) dx = \left[ \frac{3}{10}x^5 + \frac{1}{6}x^3 \right]_0^1 = \frac{7}{15}$$

$$\text{Then } \text{Var}(X) = \frac{7}{15} - \left( \frac{5}{8} \right)^2 = \frac{73}{960}$$

By symmetry,  $Y$  has the same values.

$$E(XY) = \frac{3}{2} \int_0^1 \int_0^1 (x^3y + xy^3) dy dx = \frac{3}{2} \int_0^1 \left( \frac{1}{2}x^3 + \frac{1}{4}x \right) dx = \frac{3}{8}$$

$$\text{cov}(X, Y) = \frac{3}{8} - \left( \frac{5}{8} \right)^2 = -\frac{1}{64}$$

$$\text{Var}(X + Y) = \frac{73}{960} + \frac{73}{960} - \frac{2}{64} = \frac{29}{240}$$

**3.9.20**  $E(W) = E(4X + 6Y) = 4E(X) + 6E(Y) = 4np_X + 6mp_Y$

$$\text{Var}(W) = \text{Var}(4X + 6Y) = 16\text{Var}(X) + 36\text{Var}(Y) = 16np_X(1 - p_X) + 36mp_Y(1 - p_Y)$$

**3.9.21** Let  $U_i$  be the number of calls during the  $i$ -th hour in the normal nine hour work day. Then  $U = U_1 + U_2 + \dots + U_9$  is the number of calls during this nine hour period.  $E(U) = 9(7) = 63$ . For a Poisson random variable, the variance is equal to the mean, so  $\text{Var}(U) = 9(7) = 63$ . Similarly, if  $V$  is the number of calls during the off hours,  $E(V) = \text{Var}(V) = 15(4) = 60$ . Let the total cost be the random variable  $W = 50U + 60V$ . Then  $E(W) = E(50U + 60V) = 50E(U) + 60E(V) = 50(63) + 60(60) = 6750$ ;  $\text{Var}(W) = \text{Var}(50U + 60V) = 50^2\text{Var}(U) + 60^2\text{Var}(V) = 50^2(63) + 60^2(60) = 373,500$ .

**3.9.22**  $L = \sum_{i=1}^{50} B_i + \sum_{i=1}^{49} M_i$ , where  $B_i$  is the length of the  $i$ -th brick, and  $M_i$  is the thickness of the  $i$ -th mortar separation. Assume all of the  $B_i$  and  $M_i$  are independent. By Theorem 3.9.5,  $\text{Var}(L) = 50\text{Var}(B_1) + 49\text{Var}(M_1) = 50\left(\frac{1}{32}\right)^2 + 49\left(\frac{1}{16}\right)^2 = 0.240$ . Thus, the standard deviation of  $L$  is 0.490.

**3.9.23** Let  $R_i$  be the resistance of the  $i$ -th resistor,  $1 \leq i \leq 6$ . Assume the  $R_i$  are independent and each has standard deviation  $\sigma$ . Then the variance of the circuit resistance is  $\text{Var}\left(\sum_{i=1}^6 R_i\right) = 6\sigma^2$ . The circuit must have  $6\sigma^2 \leq (0.4)^2$  or  $\sigma \leq 0.163$ .

**3.9.24** Let  $p$  be the probability the gambler wins a hand. Let  $T_k$  be his winnings on the  $k$ -th hand. Then  $E(T_k) = kp$ . Also,  $E(T_k^2) = k^2p$ , so  $\text{Var}(T_k) = k^2p - (kp)^2 = k^2(p - p^2)$ . The total winnings  $T = \sum_{k=1}^n T_k$ , so  $E(T) = \sum_{k=1}^n kp = \frac{n(n+1)}{2}p$ . 
$$\text{Var}(T) = \sum_{k=1}^n k^2(p - p^2) = \frac{n(n+1)(2n+1)}{6}(p - p^2)$$

## Section 3.10: Order Statistics

$$\begin{aligned}
 3.10.1 \quad P(Y'_3 < 5) &= \int_0^5 f_{Y'_3}(y) dy = \int_0^5 \frac{4!}{(3-1)!(4-3)!} \left(\frac{y}{10}\right)^{3-1} \left(1 - \frac{y}{10}\right)^{4-3} \frac{1}{10} dy \\
 &= \frac{12}{10^4} \int_0^5 y^2 (10-y) dy = \frac{12}{10^4} \left[ \frac{10}{3} y^3 - \frac{1}{4} y^4 \right]_0^5 = \frac{12}{10^4} \left[ \frac{10}{3} 5^3 - \frac{1}{4} 5^4 \right] = 5/16
 \end{aligned}$$

$$3.10.2 \quad \text{First find } F_Y: F_Y(y) = \int_0^y 3t^2 dt = y^3. \text{ Then } P(Y'_5 > 0.75) = 1 - P(Y'_5 < 0.75).$$

$$\begin{aligned}
 \text{But } P(Y'_5 < 0.75) &= \int_0^{0.75} \frac{6!}{(5-1)!(6-5)!} (y^3)^{5-1} (1-y^3)^{6-5} 3y^2 dy \\
 &= \int_0^{0.75} \frac{6!}{4!} (y^3)^4 (1-y^3) 3y^2 dy = \int_0^{0.75} \frac{6!}{4!} (y^3)^4 (1-y^3) 3y^2 dy \\
 &= \int_0^{0.75} 90 (y^{14}) (1-y^3) dy = 90 \left[ \frac{y^{15}}{15} - \frac{y^{18}}{18} \right]_0^{0.75} = 0.052, \\
 \text{so } P(Y'_5 > 0.75) &= 1 - P(Y'_5 < 0.75) = 1 - 0.052 = 0.948.
 \end{aligned}$$

$$\begin{aligned}
 3.10.3 \quad P(Y'_2 > y_{60}) &= 1 - P(Y'_2 < y_{60}) = 1 - P(Y_1 < y_{60}, Y_2 < y_{60}) = 1 - P(Y_1 < y_{60}) P(Y_2 < y_{60}) \\
 &= 1 - (0.60)(0.60) = 0.64
 \end{aligned}$$

$$3.10.4 \quad \text{The complement of the event is } P(Y'_1 > 0.6) \cup P(Y'_5 < 0.6).$$

These are disjoint events, so their probability is  $P(Y'_1 > 0.6) + P(Y'_5 < 0.6)$ .

$$\text{But } P(Y'_1 > 0.6) = P(Y_1, Y_2, Y_3, Y_4, Y_5 > 0.6) = [P(Y > 0.6)]^5 = \left( \int_{0.6}^1 2y dy \right)^5 = (0.64)^5 = 0.107$$

$$\text{Also, } P(Y'_5 < 0.6) = P(Y_1, Y_2, Y_3, Y_4, Y_5 < 0.6) = [P(Y < 0.6)]^5 = \left( \int_0^{0.6} 2y dy \right)^5 = (0.36)^5 = 0.006$$

The desired probability is  $1 - 0.107 - 0.006 = 0.887$ .

$$3.10.5 \quad P(Y'_1 > m) = P(Y_1, \dots, Y_n > m) = \left( \frac{1}{2} \right)^n$$

$$P(Y'_n > m) = 1 - P(Y'_n < m) = 1 - P(Y_1, \dots, Y_n < m) = 1 - P(Y_1 < m) \cdot \dots \cdot P(Y_n < m) =$$

$$1 - \left(\frac{1}{2}\right)^n$$

If  $n \geq 2$ , the latter probability is greater.

**3.10.6**  $P(Y_{\min} < 0.2) = \int_0^{0.2} n f_Y(y) [1 - F_Y(y)]^{n-1} dy$  by Theorem 3.10.1. Since  $F_Y(y) = 1 - e^{-y}$ ,

$$\int_0^{0.2} n f_Y(y) [1 - F_Y(y)]^{n-1} dy = \int_0^{0.2} n e^{-y} [1 - (1 - e^{-y})]^{n-1} dy = \int_0^{0.2} n e^{-ny} dy = -e^{-ny} \Big|_0^{0.2} = 1 - e^{-0.2n}$$

But  $(1 - e^{-0.2n}) > 0.9$  if  $e^{-0.2n} < 0.1$ , which is equivalent to  $n > -\frac{1}{0.2} \ln 0.1 = 11.513$ .

The smallest  $n$  satisfying this inequality is 12.

**3.10.7**  $P(0.6 < Y'_4 < 0.7) = F_{Y'_4}(0.7) - F_{Y'_4}(0.6) = \int_{0.6}^{0.7} \frac{6!}{(4-1)!(6-4)!} y^{4-1} (1-y)^{6-4} (1) dy$  (by Theorem

$$3.10.2) = \int_{0.6}^{0.7} 60 y^3 (1-y)^2 dy = \int_{0.6}^{0.7} 60(y^3 - 2y^4 + y^5) dy = (15y^4 - 24y^5 + 10y^6) \Big|_{0.6}^{0.7}$$

$$= 0.74431 - 0.54432 = 0.19999$$

**3.10.8** First note that  $F_Y(y) = \int_0^y 2t dt = y^2$ . Then by Theorem 3.10.2,

$$f_{Y'_1}(y) = 5(2y)(1-y^2)^{5-1} = 10y(1-y^2)^4. \text{ By this same result, } f_{Y'_5}(y) = 5(2y)(y^2)^{5-1} = 10y^9.$$

**3.10.9**  $P(Y_{\min} > 20) = P(Y_1 > 20, Y_2 > 20, \dots, Y_n > 20) = P(Y_1 > 20)P(Y_2 > 20) \dots P(Y_n > 20) = [P(Y > 20)]^n$ . But 20 is the median of  $Y$ , so  $P(Y > 20) = 1/2$ . Thus,  $P(Y_{\min} > 20) = (1/2)^n$ .

**3.10.10**  $P(Y_{\min} = Y_n) = P(Y_n < Y_1, Y_n < Y_2, \dots, Y_n < Y_{n-1}) = P(Y_n < Y_1)P(Y_n < Y_2) \dots P(Y_n < Y_{n-1}) = \left(\frac{1}{2}\right)^n$

**3.10.11** The graphed pdf is the function  $f_Y(y) = 2y$ , so  $F_Y(y) = y^2$

Then  $f_{Y'_4}(y) = 20y^6(1-y^2)2y = 40y^7(1-y^2)$  and  $F_{Y'_4}(y) = 5y^8 - 4y^{10}$ .

$$P(Y'_4 > 0.75) = 1 - F_{Y'_4}(0.75) = 1 - 0.275 = 0.725$$

The probability that none of the schools will have fewer than 10% of their students based is

$$P(Y_{\min} > 0.1) = 1 - F_{Y_{\min}}(0.1) = 1 - \int_0^{0.1} 10y(1-y^2)^4 dy = 1 - \left[ -(1-y^2)^5 \right]_0^{0.1} = 0.951$$

(see Question 3.10.8).

**3.10.12** Using the solution to Question 3.10.6, we can, in a similar manner, establish that  $f_{Y_i}(y) = n\lambda e^{-n\lambda}$ . The mean of such an exponential random variable is the inverse of its parameter, or  $1/n\lambda$ .

**3.10.13** If  $Y_1, Y_2, \dots, Y_n$  is a random sample from the uniform distribution over  $[0, 1]$ , then by Theorem

$$3.10.2, \text{ the quantity } \frac{n!}{(i-1)!(n-i)!} [F_Y(y)]^{i-1} [1-F_Y(y)]^{n-i} f_Y(y) = \frac{n!}{(i-1)!(n-i)!} y^{i-1} (1-y)^{n-i}$$

is the pdf of the  $i$ -th order statistic.

$$\text{Thus, } 1 = \int_0^1 \frac{n!}{(i-1)!(n-i)!} y^{i-1} (1-y)^{n-i} dy = \frac{n!}{(i-1)!(n-i)!} \int_0^1 y^{i-1} (1-y)^{n-i} dy \text{ or,}$$

$$\text{equivalently, } \int_0^1 y^{i-1} (1-y)^{n-i} dy = \frac{(i-1)!(n-i)!}{n!}.$$

$$\begin{aligned} \mathbf{3.10.14} \quad E(Y_i) &= \int_0^1 y \cdot \frac{n!}{(i-1)!(n-i)!} y^{i-1} (1-y)^{n-i} dy = \frac{n!}{(i-1)!(n-i)!} \int_0^1 y^i (1-y)^{n-i} dy \\ &= \frac{n!}{(i-1)!(n-i)!} \int_0^1 y^{(i+1)-1} (1-y)^{(n+1)-(i+1)} dy = \frac{n!}{(i-1)!(n-i)!} \frac{[(i+1)-1]![(n+1)-(i+1)]!}{(n+1)!} \end{aligned}$$

where this last equality comes from the result in Question 3.10.13.

$$\text{Thus, } E(Y_i) = \frac{n!}{(i-1)!(n-i)!} \frac{i!(n-i)!}{(n+1)!} = \frac{i}{(n+1)}$$

**3.10.15** This question translates to asking for the probability that a random sample of three independent uniform random variables on  $[0, 1]$  has range  $R \leq 1/2$ . Example 3.10.6 establishes that  $F_R(r) = 3r^2 - 2r^3$ . The desired probability is  $F_R(1/2) = 3(1/2)^2 - 2(1/2)^3 = 0.5$ .

**3.10.16** This question requires finding the probability that a random sample of three independent exponential random variables on  $[0, 10]$  has range  $R \leq 2$ . From Equation 3.10.5, we find the

joint pdf of  $Y_{\min}$  and  $Y_{\max}$  to be  $3[F_Y(v) - F_Y(u)]f_Y(u)f_Y(v) = 3[(1 - e^{-v}) - (1 - e^{-u})]e^{-u}e^{-v}$   
 $= 3(e^{-2u-v} - e^{-u-2v}), u \leq v$ .

$P(R \leq 2)$  is obtained by integrating the joint pdf over a strip such as pictured in Figure 3.10.4,

but the strip is infinite in extent. Thus,  $P(R \leq 2) = \int_0^\infty \int_u^{u+2} 3(e^{-2u-v} - e^{-u-2v}) dv du$ .

$$\begin{aligned} \text{The inner integral is } \int_u^{u+2} (e^{-2u-v} - e^{-u-2v}) dv &= e^{-2u} (-e^{-v}) \Big|_u^{u+2} - e^{-u} \left( -\frac{1}{2} e^{-2v} \right) \Big|_u^{u+2} \\ &= e^{-2u} (e^{-u} - e^{-u-2}) - \frac{1}{2} e^{-u} (e^{-2u} - e^{-2u-4}) = e^{-3u} \left( \frac{1}{2} - e^{-2} + \frac{1}{2} e^{-4} \right) \end{aligned}$$

$$\text{Then } P(R \leq 2) = 3 \left( \frac{1}{2} - e^{-2} + \frac{1}{2} e^{-4} \right) \int_0^\infty e^{-3u} du = \frac{1}{2} - e^{-2} + \frac{1}{2} e^{-4} = 0.374.$$

## Section 3.11: Conditional Densities

$$3.11.1 \quad p_X(x) = \frac{x+1+x \cdot 1}{21} + \frac{x+2+x \cdot 2}{21} = \frac{3+5x}{21}, x = 1, 2$$

$$p_{Y|x}(y) = \frac{p_{X,Y}(x,y)}{p_X(x)} = \frac{x+y+xy}{3+5x}, y = 1, 2$$

3.11.2 The probability that  $X=x$  and  $Y=y$  is the probability of  $y$  4's on the first two rolls and  $x-y$  rolls on the last four rolls. These events are independent, so

$$p_{X,Y}(x,y) = \binom{2}{y} \left( \frac{1}{6} \right)^y \left( \frac{5}{6} \right)^{2-y} \binom{4}{x-y} \left( \frac{1}{6} \right)^{x-y} \left( \frac{5}{6} \right)^{4-x+y} \quad \text{for } y \leq x$$

$$\text{Then } p_{Y|x}(y) = \frac{p_{X,Y}(x,y)}{p_X(x)} = \frac{\binom{2}{y} \left( \frac{1}{6} \right)^y \left( \frac{5}{6} \right)^{2-y} \binom{4}{x-y} \left( \frac{1}{6} \right)^{x-y} \left( \frac{5}{6} \right)^{4-x+y}}{\binom{6}{x} \left( \frac{1}{6} \right)^x \left( \frac{5}{6} \right)^{6-x}} = \frac{\binom{2}{y} \binom{4}{x-y}}{\binom{6}{x}},$$

$0 \leq y \leq \min(2, x)$ , which we recognize as a hypergeometric distribution.

$$3.11.3 \quad p_{Y|X}(y) = \frac{p_{X,Y}(x,y)}{p_X(x)} = \frac{\binom{8}{x}\binom{6}{y}\binom{4}{3-x-y}}{\binom{18}{3}} \div \frac{\binom{8}{x}\binom{10}{3-x}}{\binom{18}{3}} = \frac{\binom{6}{y}\binom{4}{3-x-y}}{\binom{10}{3-x}}, \text{ with } 0 \leq y \leq 3-x$$

$$3.11.4 \quad P(X=2|Y=2) = \frac{P(X=2,Y=2)}{P(Y=2)} = \frac{\binom{4}{2}\binom{4}{2}\binom{44}{1}}{\binom{52}{5}} \div \frac{\binom{4}{2}\binom{48}{3}}{\binom{52}{5}} = \frac{\binom{4}{2}\binom{4}{2}\binom{44}{1}}{\binom{4}{2}\binom{48}{3}} = 0.015$$

$$3.11.5 \quad (a) \quad 1/k = \sum_{x=1}^3 \sum_{y=1}^3 (x+y) = 36, \text{ so } k = 1/36$$

$$(b) \quad p_X(x) = \frac{1}{36} \sum_{y=1}^3 (x+y) = \frac{1}{36} (3x+6)$$

$$p_{Y|X}(1) = \frac{p_{X,Y}(x,1)}{p_X(x)} = \frac{\frac{1}{36}(x+1)}{\frac{1}{36}(3x+6)} = \frac{x+1}{3x+6}, x = 1, 2, 3$$

$$3.11.6 \quad (a) \quad p_{X,Y}(x,y) = p_{Y|X}(y)p_X(x) = \binom{x}{y} \left(\frac{1}{2}\right)^x \left(\frac{1}{3}\right), \quad y \leq x$$

$$(b) \quad p_Y(0) = \left(\frac{1}{3}\right) \sum_{x=1}^3 \binom{x}{0} \left(\frac{1}{2}\right)^x = \frac{7}{24}$$

$$p_Y(1) = \left(\frac{1}{3}\right) \sum_{x=1}^3 \binom{x}{1} \left(\frac{1}{2}\right)^x = \frac{11}{24}$$

$$p_Y(2) = \left(\frac{1}{3}\right) \sum_{x=2}^3 \binom{x}{2} \left(\frac{1}{2}\right)^x = \frac{5}{24}$$

$$p_Y(3) = \left(\frac{1}{3}\right) \binom{3}{3} \left(\frac{1}{2}\right)^3 = \frac{1}{24}$$

$$\begin{aligned}
 3.11.7 \quad p_Z(z) &= \frac{1 \cdot 1 + 1 \cdot z + 1 \cdot z}{54} + \frac{1 \cdot 2 + 1 \cdot z + 2 \cdot z}{54} + \frac{2 \cdot 1 + 2 \cdot z + 1 \cdot z}{54} + \frac{2 \cdot 2 + 2 \cdot z + 2 \cdot z}{54} \\
 &= \frac{9 + 12z}{54}, \quad z = 1, 2
 \end{aligned}$$

$$\text{Then } p_{X,Y|Z}(x,y) = \frac{xy + xz + yz}{9 + 12z}, \quad x = 1, 2 \quad y = 1, 2 \quad z = 1, 2$$

$$3.11.8 \quad p_{W,X}(1, 1) = P(\{(1, 1, 1)\}) = 3/54$$

$p_{W,X}(2, 2) = 33/54$ ;  $P(W = 2, X = 2) = P(X = 2)$ . But  $P(X = 2) = P(Z = 2)$  by symmetry, and from Question 3.11.7, this probability is  $33/54$ . Then  $p_{W,X}(2, 1) = 1 - 3/54 - 33/54 = 18/54$

Finally,  $p_{W|1}(1) = (3/54)/(21/54) = 1/7$ ;  $p_{W|1}(2) = (18/54)/(21/54) = 6/7$ ; and

$$p_{W|2}(2) = (33/54)/(33/54) = 1$$

$$\begin{aligned}
 3.11.9 \quad p_{X|X+Y=n}(x) &= \frac{P(X = k, X + Y = n)}{P(X + Y = n)} = \frac{P(X = k, Y = n - k)}{P(X + Y = n)} \\
 &= \frac{e^{-\lambda} \frac{\lambda^k}{k!} e^{-\mu} \frac{\mu^{n-k}}{(n-k)!}}{e^{-(\lambda+\mu)} \frac{(\lambda+\mu)^n}{n!}} = \frac{n!}{k!(n-k)!} \left( \frac{\lambda}{\lambda+\mu} \right)^k \left( \frac{\mu}{\lambda+\mu} \right)^{n-k} \quad \text{but the right hand term is a binomial}
 \end{aligned}$$

probability with parameters  $n$  and  $\lambda/(\lambda + \mu)$ .

3.11.10 Let  $U$  be the number of errors made by Compositor A in the 100 pages. Then the pdf of  $U$  is Poisson with parameter  $\lambda = 200$ . Similarly, if  $V$  is the number of errors made by Compositor B, then the pdf for  $V$  is Poisson with  $\mu = 300$ . From the previous question,  $P(U \leq 259 | U + V = 520)$  is binomial with parameter  $n = 520$  and  $p = 200/(200 + 300) = 2/5$ . The desired probability is

$$\sum_{k=0}^{259} \binom{520}{k} \left( \frac{2}{5} \right)^k \left( \frac{3}{5} \right)^{520-k}$$

$$\begin{aligned}
 3.11.11 \quad P(X > s + t | X > t) &= \frac{P(X > s + t \text{ and } X > t)}{P(X > t)} = \frac{P(X > s + t)}{P(X > t)} \\
 &= \frac{(1/\lambda) \int_{s+t}^{\infty} e^{-x/\lambda} dx}{(1/\lambda) \int_t^{\infty} e^{-x/\lambda} dx} = \frac{-(1/\lambda) e^{-x/\lambda} \Big|_{s+t}^{\infty}}{-(1/\lambda) e^{-x/\lambda} \Big|_t^{\infty}} = \frac{(1/\lambda) e^{-(s+t)/\lambda}}{(1/\lambda) e^{-t/\lambda}} = e^{-s/\lambda} = \int_s^{\infty} (1/\lambda) e^{-x/\lambda} dx \\
 &= P(X > s)
 \end{aligned}$$

$$3.11.12 \quad (a) \ f_X(x) = \int_x^{\infty} 2e^{-x} e^{-y} dy = 2e^{-2x}, x > 0, \text{ so } P(X < 1) = \int_0^1 2e^{-2x} dx = 1 - e^{-2} = 1 - 0.135 = 0.865$$

$$\text{Also, } P(X < 1, Y < 1) = \int_0^1 \int_0^x 2e^{-(x+y)} dy dx = \int_0^1 2e^{-x} [-e^{-y}]_0^x dx = \int_0^1 (2e^{-x} - 2e^{-2x}) dx$$

$$= -2e^{-x} + e^{-2x} \Big|_0^1 = 0.400. \text{ Then the conditional probability is } \frac{0.400}{0.865} = 0.462$$

(b)  $P(Y < 1 | X = 1) = 0$ , since the joint pdf is defined with  $y$  always larger than  $x$ .

$$(c) \ f_{Y|X}(y) = \frac{f_{X,Y}(x,y)}{f_X(x)} = \frac{2e^{-(x+y)}}{2e^{-2x}} = e^x e^{-y}, \ x < y$$

$$3.11.13 \quad f_X(x) = \int_0^1 (x+y) dy = xy + \frac{y^2}{2} \Big|_0^1 = x + \frac{1}{2}, \ 0 \leq x \leq 1$$

$$f_{Y|X}(y) = \frac{f_{X,Y}(x,y)}{f_X(x)} = \frac{x+y}{x + \frac{1}{2}}, \ 0 \leq y \leq 1$$

$$3.11.14 \quad f_X(x) = \int_0^{1-x} 2 dy = 2y \Big|_0^{1-x} = 2(1-x), \ 0 \leq x \leq 1$$

$$f_{Y|X}(y) = \frac{f_{X,Y}(x,y)}{f_X(x)} = \frac{2}{2(1-x)} = \frac{1}{1-x}, \ 0 \leq y \leq 1-x$$

For each  $x$ , the conditional pdf does not depend on  $y$ , so it is a uniform pdf.

$$3.11.15 \quad f_{X,Y}(x, y) = f_{Y|X}(y)f_X(x) = \left(\frac{2y+4x}{1+4x}\right)\frac{1}{3}(1+4x) = \frac{1}{3}(2y+4x)$$

$$f_Y(y) = \int_0^1 \frac{1}{3}(2y+4x)dx = \frac{1}{3}(2xy+2x^2)\Big|_0^1 = \frac{1}{3}(2y+2), \text{ with } 0 \leq y \leq 1$$

$$3.11.16 \quad (a) \quad f_X(x) = \int_0^1 \frac{2}{5}(2x+3y)dy = \frac{2}{5}\left(2xy + \frac{3}{2}y^2\right)\Big|_0^1 = \frac{4}{5}x + \frac{3}{5}, \text{ with } 0 \leq x \leq 1$$

$$(b) \quad f_{Y|X}(y) = \frac{\frac{2}{5}(2x+3y)}{\frac{4}{5}x + \frac{3}{5}} = \frac{4x+6y}{4x+3}, \quad 0 \leq y \leq 1$$

$$(c) \quad f_{Y|X}(y) = \frac{1}{5}(2+6y)$$

$$P(1/4 \leq Y \leq 3/4) = \int_{1/4}^{3/4} \frac{1}{5}(2+6y)dy = 10/20 = 1/2$$

$$(d) \quad E(Y|X) = \int_0^1 y \cdot f(Y|X)dy = \int_0^1 y \cdot \frac{4x+6y}{4x+3}dy = \int_0^1 y \cdot \frac{4x+6y}{4x+3}dy = \frac{1}{4x+3} \int_0^1 (4xy+6y^2)dy$$

$$= \frac{2(x+1)}{4x+3}$$

$$3.11.17 \quad f_Y(y) = \int_0^y 2dx = 2y$$

$$f_{X|Y}(x) = \frac{2}{2y} = \frac{1}{y}, \quad 0 < x < y$$

$$f_{X|Y}(x) = \frac{1}{3} = \frac{4}{3}, \quad 0 < x < 3/4$$

$$P(0 < X < 1/2 | Y = 3/4) = \int_0^{1/2} \frac{4}{3}dx = \frac{2}{3}$$

$$3.11.18 \quad f_Y(y) = \int_0^y \frac{xy}{2} dx = \frac{x^2 y}{4} \Big|_0^y = \frac{y^3}{4}, \quad 0 < y < 2$$

$$f_{X|Y}(x) = \frac{xy}{2} \Big/ \frac{y^3}{4} = \frac{2x}{y^2}, \quad 0 < x < y$$

$$f_{X|Y=3/2}(x) = \frac{2x}{(3/2)^2} = \frac{8}{9}x, \quad 0 < x < 3/2$$

$$P(X < 1 | Y = 3/2) = \int_0^1 \frac{8}{9}x \, dx = \frac{4}{9}x^2 \Big|_0^1 = \frac{4}{9}$$

$$3.11.19 \quad f_{X_4, X_5}(x_4, x_5) = \int_0^1 \int_0^1 \int_0^1 32x_1x_2x_3x_4x_5 \, dx_1dx_2dx_3 = 4x_4x_5, \quad 0 < x_4, x_5 < 1$$

$$f_{X_1, X_2, X_3 | X_4, X_5}(x_1, x_2, x_3) = \frac{32x_1x_2x_3x_4x_5}{4x_4x_5} = 8x_1x_2x_3, \quad 0 < x_1, x_2, x_3 < 1$$

Note: The five random variables are independent, so the conditional pdfs are just the marginal pdfs.

$$3.11.20 \quad (a) \quad f_X(x) = \int_0^2 \frac{6}{7} \left( x^2 + \frac{xy}{2} \right) dy = \frac{6}{7} \left( x^2 y + \frac{xy^2}{4} \right) \Big|_0^2 = \frac{6}{7}(2x^2 + x)$$

$$(b) \quad P(X > 2Y) = \int_0^1 \int_0^{\frac{1}{2}x} \frac{6}{7} \left( x^2 + \frac{xy}{2} \right) dy dx = \int_0^1 \left[ \frac{6}{7} \left( x^2 y + \frac{xy^2}{4} \right) \right]_0^{\frac{1}{2}x} dx = \int_0^1 \frac{6}{7} \left( \frac{9}{16}x^3 \right) dx = \frac{27}{224}$$

$$(c) \quad P(X > 1/2, Y > 1) = \frac{P(X > 1/2, Y > 1)}{P(X > 1/2)}$$

$$\text{First calculate the numerator: } P(X > 1/2, Y > 1) = \int_{1/2}^1 \int_1^2 \frac{6}{7} \left( x^2 + \frac{xy}{2} \right) dy dx = \frac{55}{112}$$

$$\text{We know } f_X \text{ from part (a) so the denominator is } P(X > 1/2) = \int_{1/2}^1 \frac{6}{7}(2x^2 + x) dx = \frac{23}{28}$$

$$\text{The conditional probability requested is } \frac{55}{112} \Big/ \frac{23}{28} = \frac{55}{92}.$$

**3.11.21**  $E(Y|x) = \int_{-\infty}^{\infty} y \frac{f_{X,Y}(x,y)}{f_X(x)} dy$  is a function of  $x$ . Then the expected value of this function with

regard to  $x$  is  $E(Y|x) = \int_{-\infty}^{\infty} x \left( \int_{-\infty}^{\infty} y \frac{f_{X,Y}(x,y)}{f_X(x)} dy \right) f_X(x) dx = \int_{-\infty}^{\infty} y \left( \int_{-\infty}^{\infty} f_{X,Y}(x,y) dx \right) dy$

$$\int_{-\infty}^{\infty} y \cdot f_Y(y) dy = E(Y)$$

## Section 3.12: Moment-Generating Functions

**3.12.1** Let  $X$  be a random variable with  $p_X(k) = 1/n$ , for  $k = 0, 1, 2, \dots, n-1$ , and 0 otherwise.

$$M_X(t) = E(e^{tX}) = \sum_{k=0}^{n-1} e^{tk} p_X(k) = \sum_{k=0}^{n-1} e^{tk} \frac{1}{n} = \frac{1}{n} \sum_{k=0}^{n-1} (e^t)^k = \frac{1 - e^{nt}}{n(1 - e^t)}.$$

$$(\text{Recall that } 1 + r + \dots + r^{n-1} = \frac{1 - r^n}{1 - r}).$$

**3.12.2**  $f_X(-3) = 6/10$ ;  $f_X(5) = 4/10$ .

$$M_X(t) = E(e^{tX}) = e^{-3t}(6/10) + e^{5t}(4/10)$$

**3.12.3** For the given binomial random variable,  $E(e^{tX}) = M_X(t) = \left(1 - \frac{1}{3} + \frac{1}{3}e^t\right)^{10}$ .

$$\text{Set } t = 3 \text{ to obtain } E(e^{3X}) = \frac{1}{3^{10}}(2 + e^3)^{10}$$

**3.12.4**  $M_X(t) = \sum_{k=0}^{\infty} e^{tk} \left(\frac{1}{4}\right) \left(\frac{3}{4}\right)^k = \frac{1}{4} \sum_{k=0}^{\infty} \left(\frac{3e^t}{4}\right)^k = \frac{1}{4} \frac{1}{1 - \frac{3e^t}{4}} = \frac{1}{4 - 3e^t}, 0 < e^t < 4/3$

**3.12.5** (a) Normal with  $\mu = 0$  and  $\sigma^2 = 12$

(b) Exponential with  $\lambda = 2$

(c) Binomial with  $n = 4$  and  $p = 1/2$

(d) Geometric with  $p = 0.3$

$$\begin{aligned}
3.12.6 \quad M_Y(t) &= E(e^{tY}) = \int_0^1 e^{ty} y \, dy + \int_1^2 e^{ty} (2-y) \, dy = \left( \frac{1}{t} y - \frac{1}{t^2} \right) e^{ty} \Big|_0^1 + \frac{2}{t} e^{ty} \Big|_1^2 - \left( \frac{1}{t} y - \frac{1}{t^2} \right) e^{ty} \Big|_1^2 \\
&= \left( \frac{1}{t} - \frac{1}{t^2} \right) e^t - \left( -\frac{1}{t^2} \right) + \frac{2}{t} e^{2t} - \frac{2}{t} e^t - \left( \frac{2}{t} - \frac{1}{t^2} \right) e^{2t} + \left( \frac{1}{t} - \frac{1}{t^2} \right) e^t \\
&= \frac{1}{t^2} + \frac{1}{t^2} e^{2t} - \frac{2}{t^2} e^t = \frac{1}{t^2} (e^t - 1)^2
\end{aligned}$$

$$3.12.7 \quad M_X(t) = E(e^{tX}) = \sum_{k=0}^{\infty} e^{tk} e^{-\lambda} \frac{\lambda^k}{k!} = e^{-\lambda} \sum_{k=0}^{\infty} \frac{(\lambda e^t)^k}{k!} = e^{\lambda(e^t - 1)}$$

$$\begin{aligned}
3.12.8 \quad M_Y(t) &= E(e^{tY}) = \int_0^{\infty} e^{ty} y e^{-y} \, dy = \int_0^{\infty} y e^{-y(1-t)} \, dy = \frac{1}{1-t} \int_0^{\infty} y(1-t) e^{-y(1-t)} \, dy \\
&= \left( \frac{1}{1-t} \right) \left( \frac{1}{1-t} \right) = \frac{1}{(1-t)^2}, \text{ since the integral is the mean of an exponential pdf with parameter} \\
&\quad (1-t), \text{ which is } \frac{1}{1-t}.
\end{aligned}$$

$$\begin{aligned}
3.12.9 \quad M_Y^{(1)}(t) &= \frac{d}{dt} e^{t^2/2} = t e^{t^2/2} \\
M_Y^{(2)}(t) &= \frac{d}{dt} t e^{t^2/2} = t(t e^{t^2/2}) + e^{t^2/2} = (t^2 + 1) e^{t^2/2} \\
M_Y^{(3)}(t) &= \frac{d}{dt} (t^2 + 1) e^{t^2/2} = (t^2 + 1) t e^{t^2/2} + 2t e^{t^2/2}, \text{ and } E(Y^3) = M_Y^{(3)}(0) = 0
\end{aligned}$$

$$3.12.10 \quad \text{From Example 3.12.3, } M_Y(t) = \frac{\lambda}{(\lambda - t)} \text{ and } M_Y^{(1)}(t) = \frac{\lambda}{(\lambda - t)^2}.$$

$$\text{Successive differentiation gives } M_Y^{(4)}(t) = \frac{(4!)\lambda}{(\lambda - t)^5}. \text{ Then } E(Y^4) = M_Y^{(4)}(0) = \frac{(4!)\lambda}{\lambda^5} = \frac{24}{\lambda^4}.$$

**3.12.11**  $M_Y^{(1)}(t) = \frac{d}{dt} e^{at+b^2t^2/2} = (a+b^2t)e^{at+b^2t^2/2}$ , so  $M_Y^{(1)}(0) = a$

$M_Y^{(2)}(t) = (a+b^2t)^2 e^{at+b^2t^2/2} + b^2 e^{at+b^2t^2/2}$ , so  $M_Y^{(2)}(0) = a^2 + b^2$ .

Then  $\text{Var}(Y) = (a^2 + b^2) - a^2 = b^2$

**3.12.12** Successive differentiation of  $M_Y(t)$  gives  $M_Y^{(4)}(t) = \alpha^4 k(k+1)(k+2)(k+3)(1-\alpha t)^{-k-4}$ .

Thus,  $E(Y^4) = M_Y^{(4)}(0) = \alpha^4 k(k+1)(k+2)(k+3)$

**3.12.13** The moment generating function of  $Y$  is that of a normal variable with mean  $\mu = -1$  and variance  $\sigma^2 = 8$ . Then  $E(Y^2) = \text{Var}(Y) + \mu^2 = 8 + 1 = 9$ .

**3.12.14**  $M_Y^{(1)}(t) = \frac{d}{dt} (1-t/\lambda)^{-r} = (-r)(1-t/\lambda)^{-r-1}(-\lambda) = \lambda r(1-t/\lambda)^{-r-1}$

$M_Y^{(2)}(t) = \frac{d}{dt} \lambda r(1-t/\lambda)^{-r-1} = (-r-1)\lambda r(1-t/\lambda)^{-r-2}(-\lambda) = \lambda^2 r(r+1)(1-t/\lambda)^{-r-2}$

Continuing in this manner yields  $M_Y^{(k)}(t) = \lambda^r \frac{(r+k-1)!}{(r-1)!} (1-t/\lambda)^{-r-k}$ .

Then  $E(Y^k) = M_Y^{(k)}(0) = \lambda^r \frac{(r+k-1)!}{(r-1)!}$

**3.12.15**  $M_Y(t) = \int_a^b e^{ty} \frac{1}{b-a} dy = \frac{1}{(b-a)t} e^{ty} \Big|_a^b = \frac{1}{(b-a)t} (e^{tb} - e^{at})$  for  $t \neq 0$

$M_Y^{(1)}(t) = \frac{1}{(b-a)} \left[ \frac{be^{tb} - ae^{at}}{t} - \frac{e^{tb} - e^{at}}{t^2} \right]$

$E(Y) = \lim_{t \rightarrow 0} M_Y^{(1)}(t) = \frac{1}{(b-a)} \lim_{t \rightarrow 0} \left[ \frac{be^{tb} - ae^{at}}{t} - \frac{e^{tb} - e^{at}}{t^2} \right]$ .

Applying L'Hospital's rule gives  $E(Y) = \frac{1}{(b-a)} \left[ (b^2 - a^2) - \frac{b^2 - a^2}{2} \right] = \frac{(a+b)}{2}$

$$3.12.16 \quad M_Y^{(1)}(t) = \frac{(1-t^2)2e^{2t} - (-2t)e^{2t}}{(1-t^2)^2} = 2 \frac{(1+t-t^2)e^{2t}}{(1-t^2)^2}, \text{ so } E(Y) = M_Y^{(1)}(0) = 2.$$

$$M_Y^{(2)}(t) = \frac{2(1-t^2)^2[(1-2t)e^{2t} + 2(1+t-t^2)e^{2t}] - 2(1-t^2)(-2t)2(1+t-t^2)e^{2t}}{(1-t^2)^4} \text{ so}$$

$$M_Y^{(2)}(0) = 6. \quad \text{Thus } \text{Var}(Y) = E(Y^2) - \mu^2 = 6 - 4 = 2.$$

3.12.17 Let  $Y$  be a random variable with  $f_Y(y) = \lambda^2 y e^{-\lambda y}$ ,  $y \geq 0$ . Thus by Theorem 3.8.2  $W = Y / \lambda$

has pdf  $f_W(w) = w e^{-\lambda w}$ ,  $w \geq 0$ . Then, by Question 3.12.8  $M_W(t) = \frac{1}{(1-t)^2}$ ,  $t < 1$ , and

Theorem 3.12.3(a) gives  $M_Y(t) = M_W(t / \lambda) = \frac{1}{(1-t / \lambda)^2} = \frac{\lambda^2}{(\lambda - t)^2}$ ,  $t < \lambda$ .

$$3.12.18 \quad M_{Y_1+Y_2+Y_3}(t) = M_{Y_1}(t)M_{Y_2}(t)M_{Y_3}(t) = \left( \frac{1}{(1-t / \lambda)^2} \right)^3 = \frac{1}{(1-t / \lambda)^6}$$

3.12.19 (a) Let  $X$  and  $Y$  be two Poisson variables with parameters  $\lambda$  and  $\mu$ , respectively. Then

$$M_X(t) = e^{-\lambda + \lambda e^t} \quad \text{and} \quad M_Y(t) = e^{-\mu + \mu e^t}.$$

$$M_{X+Y}(t) = M_X(t)M_Y(t) = e^{-\lambda + \lambda e^t} e^{-\mu + \mu e^t} = e^{-(\lambda + \mu) + (\lambda + \mu)e^t}.$$

This last expression is that of a Poisson variable with parameter  $\lambda + \mu$ , which is then the distribution of  $X + Y$ .

(b) Let  $X$  and  $Y$  be two exponential variables, with parameters  $\lambda$  and  $\mu$ , respectively.

$$\text{Then } M_X(t) = \frac{\lambda}{(\lambda - t)} \quad \text{and} \quad M_Y(t) = \frac{\mu}{(\mu - t)}.$$

$$M_{X+Y}(t) = M_X(t)M_Y(t) = \frac{\lambda}{(\lambda - t)} \frac{\mu}{(\mu - t)}.$$

This last expression is not that of an exponential variable, and the distribution of  $X + Y$  is not exponential.

(c) Let  $X$  and  $Y$  be two normal variables, with parameters  $\mu_1$ ,  $\sigma_1^2$  and  $\mu_2$ ,  $\sigma_2^2$  respectively.

$$\text{Then } M_X(t) = e^{\mu_1 t + \sigma_1^2 t^2 / 2} \quad \text{and} \quad M_Y(t) = e^{\mu_2 t + \sigma_2^2 t^2 / 2}.$$

$$M_{X+Y}(t) = M_X(t)M_Y(t) = e^{\mu_1 t + \sigma_1^2 t^2 / 2} e^{\mu_2 t + \sigma_2^2 t^2 / 2} = e^{(\mu_1 + \mu_2)t + (\sigma_1^2 + \sigma_2^2)t^2 / 2}.$$

This last expression is that of a normal variable with parameters  $\mu_1 + \mu_2$  and  $\sigma_1^2$  and  $\sigma_2^2$ , which is then the distribution of  $X + Y$ .

**3.12.20** From the moment-generating function of  $X$ , we know that it is binomial with  $n = 5$  and  $p = 3/4$ . Then  $P(X \leq 2) = (1/4)^5 + 5(3/4)(1/4)^4 + 10(3/4)^2(1/4)^3 = 0.104$

**3.12.21** Let  $S = \sum_{i=1}^n Y_i$ . Then  $M_S(t) = \prod_{i=1}^n M_{Y_i}(t) = \left( e^{\mu t + \sigma^2 t^2 / 2} \right)^n = e^{n\mu t + n\sigma^2 t^2 / 2}$ .  
 $M_{\bar{Y}}(t) = M_{S/n}(t) = M_S(t/n) = e^{\mu t + (\sigma^2/n)t^2 / 2}$ . Thus  $\bar{Y}$  is normal with mean  $\mu$  and variance  $\sigma^2 / n$ .

**3.12.22** From the moment-generating function of  $W$ , we know that  $W = X + Y$ , where  $X$  is Poisson with parameter 3, and  $Y$  is binomial with parameters  $n = 4$  and  $p = 1/3$ . Also,  $X$  and  $Y$  are independent.

Then  $P(W \leq 1) = p_X(0)p_Y(0) + p_X(0)p_Y(1) + p_X(1)p_Y(0) = (e^{-3})(2/3)^4 + (e^{-3})4(1/3)(2/3)^3 + (3e^{-3})(2/3)^4 = 0.059$

**3.12.23** (a)  $M_W(t) = M_{3X}(t) = M_X(3t) = e^{-\lambda + \lambda e^{3t}}$ . This last term is not the moment-generating function of a Poisson random variable, so  $W$  is not Poisson.

(b)  $M_W(t) = M_{3X+1}(t) = e' M_X(3t) = e^t e^{-\lambda + \lambda e^{3t}}$ . This last term is not the moment-generating function of a Poisson random variable, so  $W$  is not Poisson.

**3.12.24** (a)  $M_W(t) = M_{3Y}(t) = M_Y(3t) = e^{\mu(3t) + \sigma^2(3t)^2 / 2} = e^{(3\mu)t + 9\sigma^2 t^2 / 2}$ . This last term is the moment-generating function of a normal random variable with mean  $3\mu$  and variance  $9\sigma^2$ , which is then the distribution of  $W$ .

(b)  $M_W(t) = M_{3Y+1}(t) = e' M_Y(3t) = e^t e^{\mu(3t) + \sigma^2(3t)^2 / 2} = e^{(3\mu+1)t + 9\sigma^2 t^2 / 2}$ . This last term is the moment-generating function of a normal random variable with mean  $3\mu + 1$  and variance  $9\sigma^2$ , which is then the distribution of  $W$ .

# Chapter 4: Special Distributions

## Section 4.2: The Poisson Distribution

**4.2.1**  $p = P(\text{word is misspelled}) = \frac{1}{3250}$ ;  $n = 6000$ . Let  $x$  = number of words misspelled. Using the exact binomial analysis,  $P(X = 0) = \binom{6000}{0} \left(\frac{1}{3250}\right)^0 \left(\frac{3249}{3250}\right)^{6000} = 0.158$ . For the Poisson approximation,  $\lambda = 6000 \left(\frac{1}{3250}\right) = 1.846$ , so  $P(X = 0) \doteq \frac{e^{-1.846} (1.846)^0}{0!} = 0.158$ . The agreement is not surprising because  $n$  is so large and  $p$  is so small (recall Example 4.2.1).

**4.2.2** Let  $X$  = number of prescription errors. Then  $\lambda = np = 10 \cdot \frac{905}{289,411} = 0.0313$ , and  $P(X \geq 1) = 1 - P(X = 0) \doteq 1 - \frac{e^{-0.0313} (0.0313)^0}{0!} = 0.031$ .

**4.2.3** Let  $X$  = number born on Poisson's birthday. Since  $n = 500$ ,  $p = \frac{1}{365}$ , and  $\lambda = 500 \cdot \frac{1}{365} = 1.370$ ,  $P(X \leq 1) = P(X = 0) + P(X = 1) \doteq \frac{e^{-1.370} (1.370)^0}{0!} + \frac{e^{-1.370} (1.370)^1}{1!} = 0.602$ .

**4.2.4** (a) Let  $X$  = number of chromosome mutations. Given that  $n = 20,000$  and  $p = \frac{1}{10,000}$  (so  $\lambda = 2$ ),  $P(X = 3) \doteq e^{-2} 2^3 / 3! = 0.18$ .  
(b) Listed in the table are values of  $P(X \geq k)$  under the assumption that  $p = \frac{1}{10,000}$ . If  $X$  is on the order of 5 or 6, the credibility of that assumption becomes highly questionable.

$k$	$P(X \geq k)$
3	0.3233
4	0.1429
5	0.0527
6	0.0166

**4.2.5** Let  $X$  = number of items requiring a price check. If  $p = P(\text{item requires price check}) = 0.01$  and  $n = 10$ , a binomial analysis gives  $P(X \geq 1) = 1 - P(X = 0) = 1 - \binom{10}{0} (0.01)^0 (0.99)^{10} = 0.10$ . Using the Poisson approximation,  $\lambda = 10(0.01) = 0.1$  and  $P(X \geq 1) = 1 - P(X = 0) \doteq 1 - \frac{e^{-0.1} (0.1)^0}{0!} = 0.10$ . The exact model that applies here is the hypergeometric, rather than the binomial, because  $p$  is a function of the previous items purchased. However, the variation

in  $p$  will be essentially zero for the 10 items purchased, so the binomial and hypergeometric models in this case will be effectively the same.

**4.2.6** Let  $X$  = number of policy-holders who will die next year. Since  $n = 120$ ,  $p = \frac{1}{150}$ , and

$$\lambda = \frac{120}{150} = 0.8, P(\text{company will pay at least \$150,000 in benefits}) = P(X \geq 3) \\ = 1 - P(X \leq 2) \doteq 1 - \sum_{k=0}^2 \frac{e^{-0.8} (0.8)^k}{k!} = 0.047.$$

**4.2.7** Let  $X$  = number of pieces of luggage lost. Given that  $n = 120$ ,  $p = \frac{1}{200}$ ,

$$(\text{so } \lambda = 120 \cdot \frac{1}{200} = 0.6), P(X \geq 2) = 1 - P(X \leq 1) = 1 - \sum_{k=0}^1 \frac{e^{-0.6} (0.6)^k}{k!} = 0.122.$$

**4.2.8** Let  $X$  = number of cancer cases. If  $n = 9500$  and  $p = \frac{1}{1,000,000}$ , then  $\lambda = \frac{9,500}{1,000,000}$

$$= 0.0095 \text{ and } P(X \geq 2) = 1 - P(X \leq 1) = 1 - \sum_{k=0}^1 \frac{e^{-0.0095} (0.0095)^k}{k!} = 0.00005. \text{ The fact that the}$$

latter is so small suggests that a lineman's probability of contracting cancer is considerably higher than the one in a million value for  $p$  characteristic of the general population.

**4.2.9** Let  $X$  = number of solar systems with intelligent life and let  $p = P(\text{solar system is inhabited})$ . For  $n = 100,000,000,000$ ,

$$P(X \geq 1) = 1 - P(X = 0) = 1 - \binom{100,000,000,000}{0} p^0 \cdot (1-p)^{100,000,000,000}.$$

Solving  $1 - (1-p)^{100,000,000,000} = 0.50$  gives  $p = 6.9 \times 10^{-12}$ . Alternatively, it must be true that  $1 - \frac{e^{-\lambda} \lambda^0}{0!} = 0.50$ , which implies that  $\lambda = -\ln(0.50) = 0.69$ . But  $0.69 = np = 1 \times 10^{11} \cdot p$ , so  $p = 6.9 \times 10^{-12}$ .

**4.2.10** The average number of fatalities per corps-year =  $\frac{109(0) + 65(1) + 22(2) + 3(3) + 1(4)}{200} = 0.61$ ,

so the presumed Poisson model is  $p_X(k) = \frac{e^{-0.61} (0.61)^k}{k!}$ ,  $k = 0, 1, \dots$

Evaluating  $p_X(k)$  for  $k = 0, 1, 2, 3$ , and  $4+$  shows excellent agreement between the observed proportions and the corresponding Poisson probabilities.

No. of deaths, $k$	Frequency	Proportion	$p_X(k)$
0	109	0.545	0.5434
1	65	0.325	0.3314
2	22	0.110	0.1011
3	3	0.015	0.0206
4+	<u>1</u>	<u>0.005</u>	<u>0.0035</u>
	200	1.000	1.0000

- 4.2.11** The observed number of major changes = 0.44 ( $= \bar{x} = \frac{1}{356} [237(0) + 90(1) + 22(2) + 7(3)]$ ), so the presumed Poisson model is  $p_X(k) = \frac{e^{-0.44} (0.44)^k}{k!}$ ,  $k = 0, 1, \dots$ . Judging from the agreement evident in the accompanying table between the set of observed proportions and the values for  $p_X(k)$ , the hypothesis that  $X$  is a Poisson random variable is entirely credible.

No. of changes, $k$	Frequency	Proportion	$p_X(k)$
0	237	0.666	0.6440
1	90	0.253	0.2834
2	22	0.062	0.0623
3+	<u>7</u>	<u>0.020</u>	<u>0.0102</u>
	356	1.000	1.0000

- 4.2.12** Since  $\bar{x} = \frac{1}{40} [9(0) + 13(1) + 10(2) + 5(3) + 2(4) + 1(5)] = 1.53$ ,  $p_X(k) = \frac{e^{-1.53} (1.53)^k}{k!}$ ,  $k = 0, 1, \dots$ . Yes, the Poisson appears to be an adequate model, as indicated by the close agreement between the observed proportions and the values of  $p_X(k)$ .

No. of bags lost, $k$	Frequency	Proportion	$p_X(k)$
0	9	0.225	0.2165
1	13	0.325	0.3313
2	10	0.250	0.2534
3	5	0.125	0.1293
4	2	0.050	0.0494
5+	<u>1</u>	<u>0.025</u>	<u>0.0200</u>
	40	1.000	1.0000

- 4.2.13** The average of the data is  $\frac{1}{113} [82(0) + 25(1) + 4(2) + 0(3) + 2(4)] = 0.363$ . Then use the model  $e^{-0.363} \frac{0.363^k}{k!}$ . Usual statistical practice suggests collapsing the low frequency categories, in this case,  $k = 2, 3, 4$ . The result is the following table.

No. of countires, $k$	Frequency	$p_X(k)$	Expected frequency
0	82	0.696	78.6
1	25	0.252	28.5
2+	6	0.052	5.9

The level of agreement between the observed and expected frequencies suggests that the Poisson is a good model for these data.

- 4.2.14** (a) The model  $p_X(k) = e^{-2.157} (2.157)^k / k!$ ,  $k = 0, 1, \dots$  fits the data fairly well (where  $\bar{x} = 2.157$ ), but there does appear to be a slight tendency for deaths to “cluster” — that is, the values 0, 5, 6, 7, 8, and 9 are all over-represented.

No. of deaths, $k$	Frequency	$p_X(k)$	Expected frequency
0	162	0.1157	126.8
1	267	0.2495	273.5
2	271	0.2691	294.9
3	185	0.1935	212.1
4	111	0.1043	114.3
5	61	0.0450	49.3
6	27	0.0162	17.8
7	8	0.0050	5.5
8	3	0.0013	1.4
9	1	0.0003	0.3
10+	0	0.0001	0.1

(b) Deaths may not be independent events in all cases, and the fatality rate may not be constant.

**4.2.15** If the mites exhibit any sort of “contagion” effect, the independence assumption implicit in the Poisson model will be violated. Here,  $\bar{x} = \frac{1}{100} [55(0) + 20(1) + \dots + 1(7)] = 0.81$ , but  $p_X(k) = e^{-0.81}(0.81)^k/k!$ ,  $k = 0, 1, \dots$  does not adequately approximate the infestation distribution.

No. of infestations, $k$	Frequency	Proportion	$p_X(k)$
0	55	0.55	0.4449
1	20	0.20	0.3603
2	21	0.21	0.1459
3	1	0.01	0.0394
4	1	0.01	0.0080
5	1	0.01	0.0013
6	0	0	0.0002
7+	1	<u>0.01</u>	<u>0.0000</u>
		1.00	1.0000

**4.2.16** Let  $X$  = number of repairs needed during an eight-hour workday. Since  $E(X) = \lambda = 8 \cdot \frac{1}{5} = 1.6$ ,  $P(\text{expenses} \leq \$100) = P(X \leq 2) = \sum_{k=0}^2 \frac{e^{-1.6}(1.6)^k}{k!} = 0.783$ .

**4.2.17** Let  $X$  = number of transmission errors made in next half-minute. Since  $E(X) = \lambda = 4.5$ ,  $P(X > 2) = 1 - P(X \leq 2) = 1 - \sum_{k=0}^2 \frac{e^{-4.5}(4.5)^k}{k!} = 0.826$ .

**4.2.18** If  $P(X = 0) = e^{-\lambda}\lambda^0/0! = e^{-\lambda} = \frac{1}{3}$ , then  $\lambda = 1.10$ . Therefore,  $P(X \geq 2) = 1 - P(X \leq 1) = 1 - e^{-1.10}(1.10)^0/0! - e^{-1.10}(1.10)^1/1! = 0.301$ .

**4.2.19** Let  $X$  = number of flaws in 40 sq. ft. Then  $E(X) = 4$  and  $P(X \geq 3) = 1 - P(X \leq 2) = 1 - \sum_{k=0}^2 \frac{e^{-4} 4^k}{k!} = 0.762$ .

**4.2.20** Let  $X$  = number of particles counted in next two minutes. Since the rate at which the particles are counted per minute is 4.017  $\left( = \frac{482}{120} \right)$ ,  $E(X) = 8.034$  and  $P(X = 3) = \frac{e^{-8.034} (8.034)^3}{3!} = 0.028$ . Now, suppose  $X$  = number of particles counted in one minute. Then  $P(3 \text{ particles are counted in next two minutes}) = P(X = 3) \cdot P(X = 0) + P(X = 2) \cdot P(X = 1) + P(X = 1) \cdot P(X = 2) + P(X = 0) \cdot P(X = 3) = 0.028$ , where  $\lambda = 4.017$ .

**4.2.21** (a) Let  $X$  = number of accidents in next five days. Then  $E(X) = 0.5$  and  $P(X = 2) = e^{-0.5} (0.5)^2 / 2! = 0.076$ .  
 (b) No.  $P(4 \text{ accidents occur during next two weeks}) = P(X = 4) \cdot P(X = 0) + P(X = 3) \cdot P(X = 1) + P(X = 2) \cdot P(X = 2) + P(X = 1) \cdot P(X = 3) + P(X = 0) \cdot P(X = 4)$ .

**4.2.22** If  $P(X = 1) = P(X = 2)$ , then  $e^{-\lambda} \lambda^1 / 1! = e^{-\lambda} \lambda^2 / 2!$ , which implies that  $2\lambda = \lambda^2$ , or, equivalently,  $\lambda = 2$ . Therefore,  $P(X = 4) = e^{-2} 2^4 / 4! = 0.09$ .

**4.2.23** 
$$P(X \text{ is even}) = \sum_{k=0}^{\infty} \frac{e^{-\lambda} \lambda^{2k}}{(2k)!} = e^{-\lambda} \left\{ 1 + \frac{\lambda^2}{2!} + \frac{\lambda^4}{4!} + \frac{\lambda^6}{6!} + \cdots \right\} = e^{-\lambda} \cdot \cosh \lambda = e^{-\lambda} \left( \frac{e^{\lambda} + e^{-\lambda}}{2} \right) = \frac{1}{2} (1 + e^{-2\lambda}).$$

**4.2.24** 
$$f_{X+Y}(w) = \sum_{k=0}^{\infty} p_k(k) p_Y(w-k) = \sum_{k=0}^w e^{-\lambda} \frac{\lambda^k}{k!} e^{-\mu} \frac{\mu^{w-k}}{(w-k)!}$$

$$= e^{-(\lambda+\mu)} \sum_{k=0}^w \frac{1}{k!(w-k)!} \lambda^k \mu^{w-k} = e^{-(\lambda+\mu)} \frac{1}{w!} \sum_{k=0}^w \frac{w!}{k!(w-k)!} \lambda^k \mu^{w-k} = e^{-(\lambda+\mu)} \frac{1}{w!} (\lambda + \mu)^w$$

The last expression is the  $w^{\text{th}}$  term of the Poisson pdf with parameter  $\lambda + \mu$ .

**4.2.25** From Definition 3.11.1 and Theorem 3.7.1,  $P(X_2 = k) = \sum_{x_1=k}^{\infty} \binom{x_1}{k} p^k (1-p)^{x_1-k} \cdot \frac{e^{-\lambda} \lambda^{x_1}}{x_1!}$ .  
 Let  $y = x_1 - k$ . Then  $P(X_2 = k) = \sum_{y=0}^{\infty} \binom{y+k}{k} p^k (1-p)^y \cdot \frac{e^{-\lambda} \lambda^{y+k}}{(y+k)!} = \frac{e^{-\lambda} (\lambda p)^k}{k!} \cdot \sum_{y=0}^{\infty} \frac{[\lambda(1-p)]^y}{y!} = \frac{e^{-\lambda} (\lambda p)^k}{k!} \cdot e^{\lambda(1-p)} = \frac{e^{-\lambda p} (\lambda p)^k}{k!}$ .

**4.2.26** (a) Yes, because the Poisson assumptions are probably satisfied—crashes are independent events and the crash rate is likely to remain constant.  
 (b) Since  $\lambda = 2.5$  crashes per year,  $P(X \geq 4) = 1 - P(X \leq 3) = 1 - \sum_{k=0}^3 \frac{e^{-2.5} (2.5)^k}{k!} = 0.24$ .  
 (c) Let  $Y$  = interval (in yrs.) between next two crashes. By Theorem 4.2.3,  $P(Y < 0.25) = \int_0^{0.25} 2.5 e^{-2.5y} dy = 1 - 0.535 = 0.465$ .

- 4.2.27** Let  $X$  = number of deaths in a week. Based on the daily death rate,  $E(X) = \lambda = 0.7$ . Let  $Y$  = interval (in weeks) between consecutive deaths.

$$\text{Then } P(Y > 1) = \int_1^{\infty} 0.7e^{-0.7y} dy = -e^{-u} \Big|_{0.7}^{\infty} = 0.50.$$

- 4.2.28** Let  $X$  = number of bulbs burning out in 1 hour. Then  $E(X) = \lambda = 0.011$ . Let  $Y$  = number of hours a bulb remains lit. Then  $P(Y < 75) = \int_0^{75} 0.011e^{-0.011y} dy = -e^{-u} \Big|_0^{0.825} = 0.56$ .

(where  $u = 0.011y$ ). Since  $n = 50$  bulbs are initially online, the expected number that will fail to last at least 75 hours is  $50 \cdot P(Y < 75)$ , or 28.

- 4.2.29** According to Theorem 4.2.3, the time between eruptions should satisfy the exponential model  $f_Y(y) = 0.027e^{-0.027y}$ . To answer the question, create a density-scaled histogram with superimposed exponential curve. The histogram requires a frequency count of the data within a set of intervals. One such choice is given in the following table.

Interval (mos), $y$	Frequency	Density
$0 \leq y < 20$	13	0.0181
$20 \leq y < 40$	9	0.0125
$40 \leq y < 60$	5	0.0069
$60 \leq y < 80$	6	0.0083
$80 \leq y < 100$	2	0.0028
$100 \leq y < 120$	0	0.0000
$120 \leq y < 140$	1	0.0014

This gives rise to the graph demonstrating the plausibility of the exponential model.

## Section 4.3: The Normal Distribution

- 4.3.1** (a) 0.5782 (b) 0.8264 (c) 0.9306 (d) 0.0000

- 4.3.2** (a)  $0.9808 - 0.5000 = 0.4808$   
 (b)  $0.4562 - 0.2611 = 0.1951$   
 (c)  $1 - 0.1446 = 0.8554 = P(Y < 1.06)$   
 (d) 0.0099  
 (e)  $P(Z \geq 4.61) < P(Z \geq 3.9) = 1 - 1.0000 = 0.0000$

**4.3.3** (a) Both are the same because of the symmetry of  $f_Z(z)$ .

(b) Since  $f_Z(z)$  is decreasing for all  $z > 0$ ,  $\int_{a-\frac{1}{2}}^{a+\frac{1}{2}} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz$  is larger than  $\int_a^{a+1} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz$ .

**4.3.4** (a)  $\int_0^{1.24} e^{-z^2/2} dz = \sqrt{2\pi} \int_0^{1.24} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz = \sqrt{2\pi} (0.8925 - 0.5000) = 1.234$

(b)  $\int_{-\infty}^{\infty} 6e^{-z^2/2} dz = 6\sqrt{2\pi} \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz = 6\sqrt{2\pi}$

**4.3.5** (a) -0.44 (b) 0.76 (c) 0.41 (d) 1.28 (e) 0.95

**4.3.6** From Appendix Table A.1,  $z_{.25} = 0.67$  and  $z_{.75} = -0.67$ , so  $Q = 0.67 - (-0.67) = 1.34$ .

**4.3.7** Let  $X$  = number of decals purchased in November. Then  $X$  is binomial with  $n = 74,806$  and  $p = 1/12$ .

$P(50X < 306,000) = P(X < 6120) = P(X \leq 6119)$ . Using the DeMoivre-Laplace approximation

with continuity correction gives  $P(X \leq 6119) \doteq P\left(Z \leq \frac{6119.5 - 74,806(1/12)}{\sqrt{74,806(1/12)(11/12)}}\right)$

$$= P(Z \leq -1.51) = 0.0655$$

**4.3.8** Let  $X$  = number of usable cabinets in next shipment. Since  $np = 1600(0.80) = 1280$  and  $\sqrt{np(1-p)} = \sqrt{1600(0.80)(0.20)} = 16$ ,  $P(\text{shipment causes no problems}) =$

$$P(1260 \leq X \leq 1310) = P\left(\frac{1259.5 - 1280}{16} \leq \frac{X - 1280}{16} \leq \frac{1310.5 - 1280}{16}\right) \doteq P(-1.28 \leq Z \leq 1.91) \\ = 0.8716.$$

**4.3.9** Let  $X$  = number of voters challenger receives. Given that  $n = 400$  and  $p = P(\text{voter favors challenger}) = 0.45$ ,  $np = 180$  and  $np(1-p) = 99$ .

(a)  $P(\text{tie}) = P(X = 200) = P(199.5 \leq X \leq 200.5) =$

$$P\left(\frac{199.5 - 180}{\sqrt{99}} \leq \frac{X - 180}{\sqrt{99}} \leq \frac{200.5 - 180}{\sqrt{99}}\right) \doteq P(1.96 \leq Z \leq 2.06) = 0.0053.$$

(b)  $P(\text{challenger wins}) = P(X > 200) = P(X \geq 200.5) = P\left(\frac{X - 180}{\sqrt{99}} \geq \frac{200.5 - 180}{\sqrt{99}}\right) \doteq$

$$P(Z \geq 2.06) = 0.0197.$$

**4.3.10** (a) Let  $X$  = number of shots made in next 100 attempts.

$$\text{Since } p = P(\text{attempt is successful}) = 0.70, P(75 \leq X \leq 80) = \sum_{k=75}^{80} \binom{100}{k} (0.70)^k (0.30)^{100-k}.$$

(b) With  $np = 100(0.70) = 70$  and  $np(1-p) = 100(0.70)(0.30) = 21$ ,  $P(75 \leq X \leq 80) =$

$$P(74.5 \leq X \leq 80.5) = P\left(\frac{74.5 - 70}{\sqrt{21}} \leq \frac{X - 70}{\sqrt{21}} \leq \frac{80.5 - 70}{\sqrt{21}}\right) = P(0.98 \leq Z \leq 2.29) = 0.1525.$$

**4.3.11** Let  $p = P(\text{person dies by chance in the three months following birthmonth}) = \frac{1}{4}$ .

Given that  $n = 747$ ,  $np = 186.75$ , and  $np(1 - p) = 140.06$ ,  $P(X \geq 344) = P(X \geq 343.5)$   
 $= P\left(\frac{X - 186.75}{\sqrt{140.06}} \geq \frac{343.5 - 186.75}{\sqrt{140.06}}\right) = P(Z \geq 13.25) = 0.0000$ . The fact that the latter probability is so small strongly discredits the hypothesis that people die randomly with respect to their birthdays.

**4.3.12** Let  $X$  = number of correct guesses (out of  $n = 1500$  attempts). Since five choices were available for each guess (recall Figure 4.3.4),  $p = P(\text{correct answer}) = 1/5$ , if ESP is not a

factor. Then  $P(X \geq 326) = P(X \geq 325.5) = P\left(\frac{X - 1500(1/5)}{\sqrt{1500(1/5)(4/5)}} \geq \frac{325.5 - 300}{\sqrt{240}}\right) \doteq$

$P(Z \geq 1.65) = 0.0495$ . Based on these results, there is certainly some evidence that ESP may be increasing the probability of a correct guess, but the magnitude of  $P(X \geq 326)$  is not so small that it precludes the possibility that chance is the only operative factor.

**4.3.13** No, the normal approximation is inappropriate because the values of  $n$  ( $= 10$ ) and  $p$  ( $= 0.7$ ) fail to satisfy the condition  $n > 9 \frac{p}{1-p} = 9 \frac{0.7}{0.3} = 21$ .

**4.3.14** Let  $X$  = number of fans buying hot dogs. To be determined is the smallest value of  $c$  for which  $P(X > c) \leq 0.20$ . Assume that no one eats more than one hot dog. Then  $X$  is a binomial random variable with  $n = 42,200$  and  $p = P(\text{fan buys hot dog}) = 0.38$ . Since  $np = 16,036$  and

$$\sqrt{np(1-p)} = 99.7, P(X > c) = 0.20 = P(X \geq c + 1) = P\left(Z \geq \frac{c + 1 - \frac{1}{2} - 16,036}{99.7}\right).$$

$$\text{But } P(Z \geq 0.8416) = 0.20, \text{ so } 0.8416 = \frac{c + 1 - \frac{1}{2} - 16,036}{99.7}, \text{ from which it follows that}$$

$$c = 16,119.$$

**4.3.15**  $P(|X - E(X)| \leq 5) = P(-5 \leq X - 100 \leq 5) = P\left(\frac{-5.5}{\sqrt{50}} \leq \frac{X - 100}{\sqrt{50}} \leq \frac{5.5}{\sqrt{50}}\right) \doteq P(-0.78 \leq Z \leq 0.78)$   
 $= 0.5646$ .

For binomial data, the central limit theorem and DeMoivre-Laplace approximations differ only if the continuity correction is used in the DeMoivre-Laplace approximation.

**4.3.16** Let  $X_i$  = face showing on  $i$ th die,  $i = 1, 2, \dots, 100$ , and let  $X = X_1 + X_2 + \dots + X_{100}$ . Following the approach taken in Example 3.9.5 gives  $E(X) = 350$ . Also,  $\text{Var}(X_i) = E(X_i^2) - [E(X_i)]^2 =$

$$\frac{1}{6}(1^2 + 2^2 + 3^2 + 4^2 + 5^2 + 6^2) - \left(3\frac{1}{2}\right)^2 = \frac{35}{12}, \text{ so } \text{Var}(X) = \frac{3500}{12}. \text{ By the central limit theorem,}$$

then,  $P(X > 370) = P(X \geq 371) = P(X \geq 370.5) = P\left(\frac{X - 350}{\sqrt{3500/12}} \geq \frac{370.5 - 350}{\sqrt{3500/12}}\right) \doteq P(Z \geq 1.20)$   
 $= 0.1151$ .

**4.3.17** For the given  $X$ ,  $E(X) = 5(18/38) + (-5)(20/38) = -10/38 = -0.263$ .  
 $\text{Var}(X) = 25(18/38) + (25)(20/38) - (-10/38)^2 = 24.931$ ,  $\sigma = 4.993$ .

Then  $P(X_1 + X_2 + \dots + X_{100} > -50)$   
 $= P\left(\frac{X_1 + X_2 + \dots + X_{100} - 100(-0.263)}{\sqrt{100}(4.993)} > \frac{-50 - 100(-0.263)}{10(4.993)}\right) \doteq P(Z > -0.47) = 1 - 0.3192$   
 $= 0.6808$

**4.3.18** (a)  $E(S) = \text{Var}(S) = 4(3) = 12$ . Use a continuity correction. Then

$$P\left(\frac{12.5 - 12}{\sqrt{12}} \leq S \leq \frac{14.5 - 12}{\sqrt{12}}\right) \doteq P(0.14 \leq Z \leq 0.72) = 0.7642 - 0.5557 = 0.2085$$

$$(b) P(13 \leq S \leq 14) = e^{-12} \left( \frac{12^{13}}{13!} + \frac{12^{14}}{14!} \right) = 0.1961$$

**4.3.19** Let  $X$  = number of chips ordered next week. Given that  $\lambda = E(X) = 50$ ,  $P(\text{company is unable to fill orders}) = P(X \geq 61) = P(X \geq 60.5) = P\left(\frac{X - 50}{\sqrt{50}} \geq \frac{60.5 - 50}{\sqrt{50}}\right) = P(Z \geq 1.48) = 0.0694$ .

**4.3.20** Let  $X$  = number of leukemia cases diagnosed among 3000 observers. If  $\lambda = E(X) = 3$ ,  
 $P(X \geq 8) = 1 - P(X \leq 7) = 1 - \sum_{k=0}^7 \frac{e^{-3} 3^k}{k!} = 1 - 0.9881 = 0.0119$ . Using the central limit

$$\text{theorem, } 1 - P(X \leq 7) = 1 - P(X \leq 7.5) = 1 - P\left(\frac{X - 3}{\sqrt{3}} \leq \frac{7.5 - 3}{\sqrt{3}}\right) \doteq 1 - P(Z \leq 2.61)$$

$= 0.0045$ . The approximation is not particularly good because  $\lambda$  is small. In general, if  $\lambda$  is less than 5, the normal approximation should not be used. Both analyses, though, suggest that the observer's risk of contracting leukemia was increased because of their exposure to the test.

**4.3.21** No, only 84% of drivers are likely to get at least 25,000 miles on the tires. If  $X$  denotes the mileage obtained on a set of Econo-Tires,

$$P(X \geq 25,000) = P\left(\frac{X - 30,000}{5000} \geq \frac{25,000 - 30,000}{5000}\right) = P(Z \geq -1.00) = 0.8413.$$

**4.3.22** Let  $Y$  denote a child's IQ. Then  $P(\text{child needs special services}) = P(Y < 80) + P(Y > 135) =$   
 $P\left(\frac{Y - 100}{16} < \frac{80 - 100}{16}\right) + P\left(\frac{Y - 100}{16} > \frac{135 - 100}{16}\right) = P(Z < -1.25) + P(Z > 2.19) =$   
 $0.1056 + 0.0143 = 0.1199$ . It follows that  $1400 \times 0.1199 \times \$1750 = \$293,755$  should be added to Westbank's special ed budget.

**4.3.23** Let  $Y$  = donations collected tomorrow. Given that  $\mu = \$20,000$  and  $\sigma = \$5,000$ ,

$$P(Y > \$30,000) = P\left(\frac{Y - \$20,000}{\$5,000} > \frac{\$30,000 - \$20,000}{\$5,000}\right) = P(Z > 2.00) = 0.0228.$$

**4.3.24** Let  $Y$  = pregnancy duration (in days). Ten months and four days is equivalent to 309 days. The plausibility of San Diego Reader's claim hinges on the magnitude of  $P(Y \geq 309)$ —the smaller that probability is, the less believable her explanation becomes. Given that  $\mu = 266$

and  $\sigma = 16$ ,  $P(Y \geq 309) = P\left(\frac{Y - 266}{16} \geq \frac{309 - 266}{16}\right) = P(Z \geq 2.69) = 0.0036$ . From a

statistical point of view, pregnancies lasting 309 or more days are extremely unlikely. A more pertinent question is whether such pregnancy durations have occurred—a medical question.

**4.3.25** (a) Let  $Y_1$  and  $Y_2$  denote the scores made by a random nondelinquent and delinquent, respectively. Then  $E(Y_1) = 60$  and  $\text{Var}(Y_1) = 10^2$ ; also,  $E(Y_2) = 80$  and  $\text{Var}(Y_2) = 5^2$ . Since 75 is the cutoff between teenagers classified as delinquents or nondelinquents,

$$P(\text{nondelinquent is misclassified as delinquent}) = P(Y_1 > 75) = P\left(Z > \frac{75 - 60}{10}\right) = 0.0668.$$

Similarly,  $P(\text{delinquent is misclassified as nondelinquent}) = P(Y_2 < 75) =$

$$P\left(Z < \frac{75 - 80}{5}\right) = 0.1587.$$

**4.3.26** Let  $Y$  denote the cross-sectional area of a tube.

Then  $p = P(\text{tube does not fit properly}) = P(Y < 12.0) + P(Y > 13.0) = 1 - P(12.0 \leq Y \leq 13.0) =$

$$1 - P\left(\frac{12.0 - 12.5}{0.2} \leq \frac{Y - 12.5}{0.2} \leq \frac{13.0 - 12.5}{0.2}\right) = 1 - P(-2.50 \leq Z \leq 2.50) = 1 - 0.9876 = 0.0124.$$

Let  $X$  denote the number of tubes (out of 1000) that will not fit. Since  $X$  is a binomial random variable,  $E(X) = np = 1000(0.0124) = 12.4$ .

**4.3.27** Let  $Y$  = freshman's verbal SAT score.

Given that  $\mu = 565$  and  $\sigma = 75$ ,  $P(Y > 660) = P\left(\frac{Y - 565}{75} > \frac{660 - 565}{75}\right) = P(Z > 1.27)$

$= 0.1020$ . It follows that the expected number doing better is  $4250(0.1020)$ , or 434.

**4.3.28** Let  $A^*$  and  $B^*$  denote the lowest A and the lowest B, respectively. Since the top 20% of the grades will be A's,  $P(Y < A^*) = 0.80$ , where  $Y$  denotes a random student's score.

Equivalently,  $P\left(Z < \frac{A^* - 70}{12}\right) = 0.80$ .

From Appendix Table A.1, though,  $P(Z < 0.84) = 0.7995 \doteq 0.80$ . Therefore,  $0.84 = \frac{A^* - 70}{12}$ ,

which implies that  $A^* = 80$ .

Similarly,  $P(Y < B^*) = 0.54 = P\left(Z < \frac{B^* - 70}{12}\right)$ . But  $P(Z < 0.10) = 0.5398 \doteq 0.54$ ,

so  $0.10 = \frac{B^* - 70}{12}$ , implying that  $B^* = 71$ .

**4.3.29** If  $P(20 \leq Y \leq 60) = 0.50$ , then  $P\left(\frac{20-40}{\sigma} \leq \frac{Y-40}{\sigma} \leq \frac{60-40}{\sigma}\right) = 0.50 = P\left(\frac{-20}{\sigma} \leq Z \leq \frac{20}{\sigma}\right)$ .

But  $P(-0.67 \leq Z \leq 0.67) = 0.4972 \doteq 0.50$ , which implies that  $0.67 = \frac{20}{\sigma}$ . The desired value for  $\sigma$ , then, is  $\frac{20}{0.67}$ , or 29.85.

**4.3.30** Let  $Y$  = a random 18-year-old woman's weight. Since  $\mu = \frac{103.5 + 144.5}{2} = 124$ ,

$$P(103.5 \leq Y \leq 144.5) = 0.80 = P\left(\frac{103.5-124}{\sigma} \leq \frac{Y-124}{\sigma} \leq \frac{144.5-124}{\sigma}\right) \\ = P\left(\frac{-20.5}{\sigma} \leq Z \leq \frac{20.5}{\sigma}\right). \text{ According to Appendix Table A.1, } P(-1.28 \leq Z \leq 1.28) \doteq 0.80, \text{ so } \\ \frac{20.5}{\sigma} = 1.28, \text{ implying that } \sigma = 16.0 \text{ lbs.}$$

**4.3.31** Let  $Y$  = analyzer reading for driver whose true blood alcohol concentration is 0.9. Then

$$P(\text{analyzer mistakenly shows driver to be sober}) = P(Y < 0.08) = P\left(\frac{Y-0.9}{0.004} < \frac{0.08-0.09}{0.004}\right)$$

$= P(Z < -2.50) = 0.0062$ . The “0.075%” driver should ask to take the test twice. The “0.09%” driver has a greater chance of not being charged by taking the test only once. As,  $n$  the number of times the test taken, increases, the precision of the average reading increases. It is to the sober driver's advantage to have a reading as precise as possible; the opposite is true for the drunk driver.

**4.3.32** The normed score for Michael is  $\frac{75-62.0}{7.6} = 1.71$ ; the normed score for Laura is  $\frac{92-76.3}{10.8} = 1.45$ . So, even though Laura made 17 points higher on the test, the company would be committed to hiring Michael.

**4.3.33** By the first corollary to Theorem 4.3.3,  $P(\bar{Y} > 103) = P\left(\frac{\bar{Y}-100}{16/\sqrt{9}} > \frac{103-100}{16/\sqrt{9}}\right) = P(Z > 0.56) \\ = 0.2877$ . For any arbitrary  $Y_i$ ,  $P(Y_i > 103) = P\left(\frac{Y_i-100}{16} > \frac{103-100}{16}\right) = P(Z > 0.19) = \\ 0.4247$ . Let  $X$  = number of  $Y_i$ 's that exceed 103. Since  $X$  is a binomial random variable with  $n = 9$  and  $p = P(Y_i > 103) = 0.4247$ ,  $P(X = 3) = \binom{9}{3}(0.4247)^3(0.5753)^6 = 0.23$ .

**4.3.34** If  $P(1.9 \leq \bar{Y} \leq 2.1) \geq 0.99$ , then  $P\left(\frac{1.9-2}{2/\sqrt{n}} \leq Z \leq \frac{2.1-2}{2/\sqrt{n}}\right) \geq 0.99$ . But  $P(-2.58 \leq Z \leq 2.58) \doteq 0.99$ , so  $2.58 = \frac{2.1-2}{2/\sqrt{n}}$ , which implies that  $n = 2663$ .

**4.3.35** Let  $Y_i$  = resistance of  $i$ th resistor,  $i = 1, 2, 3$ , and let  $Y = Y_1 + Y_2 + Y_3$  = circuit resistance. By the first corollary to Theorem 4.3.3,  $E(Y) = 6 + 6 + 6 = 18$  and  $\text{Var}(Y) = (0.3)^2 + (0.3)^2 + (0.3)^2 = 0.27$ . Therefore,  $P(Y > 19) = P\left(\frac{Y-18}{\sqrt{0.27}} > \frac{19-18}{\sqrt{0.27}}\right) = P(Z > 1.92) = 0.0274$ . Suppose

$$P(Y > 19) = 0.005 = P\left(Z > \frac{19-18}{\sqrt{3\sigma^2}}\right). \text{ From Appendix Table A.1, } P(Z > 2.58) \doteq 0.005, \text{ so}$$

$2.58 = \frac{19-18}{\sqrt{3\sigma^2}}$ , which implies that the minimum “precision” of the manufacturing process would have to be  $\sigma = 0.22$  ohms.

**4.3.36** Let  $Y_P$  and  $Y_C$  denote a random piston diameter and cylinder diameter, respectively. Then  $P(\text{pair needs to be reworked}) = P(Y_P > Y_C) = P(Y_P - Y_C > 0) =$

$$P\left(\frac{Y_P - Y_C - (40.5 - 41.5)}{\sqrt{(0.3)^2 + (0.4)^2}} > \frac{0 - (40.5 - 41.5)}{\sqrt{(0.3)^2 + (0.4)^2}}\right) = P(Z > 2.00) = 0.0228, \text{ or } 2.28\%.$$

**4.3.37**  $M_{\bar{Y}}(t) = M_{Y_1 + \dots + Y_n}\left(\frac{t}{n}\right) = \prod_{i=1}^n M_{Y_i}\left(\frac{t}{n}\right) = \prod_{i=1}^n e^{\mu t/n + \sigma^2 t^2 / 2n^2} = e^{\mu t + \sigma^2 t^2 / 2n}$ , but the latter is the moment-generating function for a normal random variable whose mean is  $\mu$  and whose variance is  $\sigma^2/n$ . Similarly, if  $Y = a_1 Y_1 + \dots + a_n Y_n$ ,  $M_Y(t)$

$$= \prod_{i=1}^n M_{a_i Y_i}(t) = \prod_{i=1}^n M_{Y_i}(a_i t) = \prod_{i=1}^n e^{\mu_i a_i t + \sigma_i^2 a_i^2 t^2 / 2} = e^{\sum_{i=1}^n a_i \mu_i t + \sum_{i=1}^n a_i^2 \sigma_i^2 t^2 / 2}. \text{ By inspection, } Y \text{ has the}$$

moment-generating function of a normal random variable for which  $E(Y) = \sum_{i=1}^n a_i \mu_i$  and

$$\text{Var}(Y) = \sum_{i=1}^n a_i^2 \sigma_i^2.$$

**4.3.38**  $P(\bar{Y} \geq \bar{Y}^*) = P(\bar{Y} - \bar{Y}^* \geq 0)$ , where  $E(\bar{Y} - \bar{Y}^*) = E(\bar{Y}) - E(\bar{Y}^*) = 2 - 1 = 1$ .

Also,  $\text{Var}(\bar{Y} - \bar{Y}^*) = \text{Var}(\bar{Y}) + \text{Var}(\bar{Y}^*) = \frac{2^2}{9} + \frac{1^2}{9} = \frac{5}{9}$ , because  $\bar{Y}$  and  $\bar{Y}^*$  are independent.

$$\text{Therefore, } P(\bar{Y} \geq \bar{Y}^*) = P\left(\frac{\bar{Y} - \bar{Y}^* - 1}{\sqrt{5/9}} \geq \frac{0 - 1}{\sqrt{5/9}}\right) = P(Z \geq -1.34) = 0.9099$$

**4.3.39** (a) Suppose  $n$  is the number of families moving to town. Then  $X$ , the number of high school students moving to town, is a Poisson random variable with parameter  $n\lambda$ . Then the estimated number of new high school students is  $E(nX) = n\lambda$ ; 400 is taken to represent this value. Then the variance of  $nX$  is 400 and the standard deviation is 20.

(b) Let  $Y$  denote a student's score on the diagnostic test.

Then  $P(\text{student needs special services}) = P(Y < 120) + P(Y > 290) =$

$$P\left(\frac{Y - 200}{40} < \frac{120 - 200}{40}\right) + P\left(\frac{Y - 200}{40} > \frac{290 - 200}{40}\right) = P(Z < -2.00) + P(Z > 2.25) =$$

$$0.0228 + 0.0122 = 0.035.$$

- (c) The estimated number of students needing special instruction is  $400 \times 0.035 = 14$ . The additional cost is  $14 \times \$1500 = \$21,000$ , so the budgeted \$20,400 will not be sufficient.

## Section 4.4: The Geometric Distribution

**4.4.1** Let  $p = P(\text{return is audited in a given year}) = 0.30$  and let  $X = \text{year of first audit}$ . Then  $P(\text{Jody escapes detection for at least 3 years}) = P(X \geq 4) = 1 - P(X \leq 3) = 1 - \sum_{k=1}^3 (0.70)^{k-1} (0.30) = 0.343$ .

**4.4.2** If  $X = \text{attempt at which license is awarded}$  and  $p = P(\text{driver passes test on any given attempt}) = 0.10$ , then  $p_X(k) = (0.90)^{k-1} (0.10)$ ,  $k = 1, 2, \dots$ ;  $E(X) = \frac{1}{p} = \frac{1}{0.10} = 10$ .

**4.4.3** No, the expected frequencies ( $= 5 \cdot p_X(k)$ ) differ considerably from the observed frequencies, especially for small values of  $k$ . The observed number of 1's, for example, is 4, while the expected number is 12.5.

$k$	Obs. Freq.	$p_X(k) = \left(\frac{3}{4}\right)^{k-1} \left(\frac{1}{4}\right)$	$50 \cdot p_X(k) = \text{Exp. freq.}$
1	4	0.2500	12.5
2	13	0.1875	9.4
3	10	0.1406	7.0
4	7	0.1055	5.3
5	5	0.0791	4.0
6	4	0.0593	3.0
7	3	0.0445	2.2
8	3	0.0334	1.7
9+	<u>1</u>	<u>0.1001</u>	<u>5.0</u>
	50	1.0000	50.0

**4.4.4** If  $p = P(\text{child is a girl})$  and  $X = \text{birth order of first girl}$ , then  $E(X) = \frac{1}{p} = \frac{1}{\frac{1}{2}} = 2$ . Barring any

medical restrictions, it would not be unreasonable to model the appearance of a couple's first girl (or boy) by the geometric probability function. The most appropriate value for  $p$ , though, would not be exactly  $\frac{1}{2}$  (although census figures indicate that it would be close to  $\frac{1}{2}$ ).

**4.4.5**  $F_X(t) = P(X \leq t) = p \sum_{s=0}^{[t]} (1-p)^s$ . But  $\sum_{s=0}^{[t]} (1-p)^s = \frac{1 - (1-p)^{[t]+1}}{1 - (1-p)} = \frac{1 - (1-p)^{[t]+1}}{p}$ , and the result follows.

**4.4.6** Let  $X$  = roll on which sum of 4 appears for first time. Since  $p = P(\text{sum} = 4) = \frac{3}{216}$ ,  $p_X(k) = \left(\frac{213}{216}\right)^{k-1} \cdot \frac{3}{216}$ ,  $k = 1, 2, \dots$ . Using the expression for  $F_X(k)$  given in Question 4.4.5, we can write  $P(65 \leq X \leq 75) = F_X(75) - F_X(64) = 1 - \left(1 - \frac{3}{216}\right)^{[75]} - \left(1 - \left(1 - \frac{3}{216}\right)^{[64]}\right) = \left(\frac{213}{216}\right)^{64} - \left(\frac{213}{216}\right)^{75} = 0.058$ .

**4.4.7**  $P(n \leq Y \leq n+1) = \int_n^{n+1} \lambda e^{-\lambda y} dy = (1 - e^{-\lambda y}) \Big|_n^{n+1} = e^{-\lambda n} - e^{-\lambda(n+1)} = e^{-\lambda n} (1 - e^{-\lambda})$   
Setting  $p = 1 - e^{-\lambda}$  gives  $P(n \leq Y \leq n+1) = (1-p)^n p$ .

**4.4.8** Let the random variable  $X^*$  denote the number of trials preceding the first success. By inspection,  $p_{X^*}(t) = (1-p)^k p$ ,  $k = 0, 1, 2, \dots$   
Also,  $M_{X^*}(t) = \sum_{k=0}^{\infty} e^{tk} \cdot (1-p)^k p = p \sum_{k=0}^{\infty} [(1-p)e^t]^k = p \cdot \left( \frac{1}{1-(1-p)e^t} \right) = \frac{p}{1-(1-p)e^t}$ . Let  $X$  denote the geometric random variable defined in Theorem 4.4.1. Then  $X^* = X - 1$ , and  $M_{X^*}(t) = e^{-t} M_X(t) = e^{-t} \cdot \frac{pe^t}{1-(1-p)e^t} = \frac{p}{1-(1-p)e^t}$ .

**4.4.9**  $M_X(t) = pe^t[1 - (1-p)e^t]^{-1}$ , so  $M_X^{(1)}(t) = pe^t(-1)[1 - (1-p)e^t]^{-2} \cdot (-(1-p)e^t) + [1 - (1-p)e^t]^{-1} pe^t$ . Setting  $t = 0$  gives  $M_X^{(1)}(0) = E(X) = \frac{1}{p}$ .  
Similarly,  $M_X^{(2)}(t) = p(1-p)e^{2t}(-2)[1 - (1-p)e^t]^{-3} \cdot (-(1-p)e^t) + [1 - (1-p)e^t]^{-2} p(1-p)e^{2t} \cdot 2 + [1 - (1-p)e^t]^{-1} pe^t + pe^t(-1)[1 - (1-p)e^t]^{-2} \cdot (-(1-p)e^t)$  and  $M_X^{(2)}(0) = E(X^2) = \frac{2-p}{p^2}$ .  
Therefore,  $\text{Var}(X) = E(X^2) - [E(X)]^2 = \frac{2-p}{p^2} - \left(\frac{1}{p}\right)^2 = \frac{1-p}{p^2}$ .

**4.4.10** No, because  $M_X(t) = M_{X_1}(t) \cdot M_{X_2}(t)$  does not have the form of a geometric moment-generating function.

**4.4.11** Let  $M_X^*(t) = E(t^X) = \sum_{k=1}^{\infty} t^k \cdot (1-p)^{k-1} p = \frac{p}{1-p} \sum_{k=1}^{\infty} [t(1-p)]^k = \frac{p}{1-p} \sum_{k=0}^{\infty} [t(1-p)]^k - \frac{p}{1-p} = \frac{p}{1-p} \left[ \frac{1}{1-t(1-p)} \right] - \frac{p}{1-p} = \frac{pt}{1-t(1-p)}$  = factorial moment-generating function for  $X$ .  
Then  $M_X^{*(1)}(t) = pt(-1)[1 - t(1-p)]^{-2}(-(1-p)) + [1 - t(1-p)]^{-1} p = \frac{p}{[1 - t(1-p)]^2}$ .  
When  $t = 1$ ,  $M_X^{*(1)}(1) = E(X) = \frac{1}{p}$ . Also,  $M_X^{*(2)}(t) = \frac{2p(1-p)}{[1 - t(1-p)]^3}$  and  $M_X^{*(2)}(1) = \frac{2-2p}{p^2}$ .

$$= E[X(X-1)] = E(X^2) - E(X). \text{ Therefore, } \text{Var}(X) = E(X^2) - [E(X)]^2 = \frac{2-2p}{p^2} + \frac{1}{p} - \left(\frac{1}{p}\right)^2$$

$$= \frac{1-p}{p^2}.$$

## Section 4.5: The Negative Binomial Distribution

**4.5.1** Let  $X$  = number of houses needed to achieve fifth invitation. If  $p = P(\text{saleswoman receives invitation at a given house}) = 0.30$ ,  $p_X(k) = \binom{k-1}{4} (0.30)^4 (0.70)^{k-1-4} (0.30)$ ,  $k = 5, 6, \dots$  and

$$P(X < 8) = P(5 \leq X \leq 7) = \sum_{k=5}^7 \binom{k-1}{4} (0.30)^5 (0.70)^{k-5} = 0.029.$$

**4.5.2** Let  $p = P(\text{missile scores direct hit}) = 0.30$ . Then  $P(\text{target will be destroyed by seventh missile fired}) = P(\text{exactly three direct hits occur among first six missiles and seventh missile scores direct hit}) = \binom{6}{3} (0.30)^3 (0.70)^3 (0.30) = 0.056$ .

**4.5.3** Darryl might have actually done his homework, but there is reason to suspect that he did not. Let the random variable  $X$  denote the toss where a head appears for the second time. Then  $p_X(k) = \binom{k-1}{1} \left(\frac{1}{2}\right)^2 \left(\frac{1}{2}\right)^{k-2}$ ,  $k = 2, 3, \dots$ , but that particular model fits the data almost perfectly, as the table shows. Agreement this good is often an indication that the data have been fabricated.

$k$	$p_X(k)$	Obs. freq.	Exp. freq.
2	1/4	24	25
3	2/8	26	25
4	3/16	19	19
5	4/32	13	12
6	5/64	8	8
7	6/128	5	5
8	7/256	3	3
9	8/512	1	2
10	9/1024	1	1

**4.5.4** Let  $p = P(\text{defective is produced by improperly adjusted machine}) = 0.15$ . Let  $X$  = item at which machine is readjusted. Then  $p_X(k) = \binom{k-1}{2} (0.15)^2 (0.85)^{k-1-2} (0.15) = \binom{k-1}{2} (0.15)^3 (0.85)^{k-3}$ ,  $k = 3, 4, \dots$

It follows that  $P(X \geq 5) = 1 - P(X \leq 4) = 1 - [P(X = 3) + P(X = 4)] = 0.988$  and

$$E(X) = \frac{3}{0.15} = 20.$$

$$4.5.5 \quad E(X) = \sum_{k=r}^{\infty} k \binom{k-1}{r-1} p^r (1-p)^{k-r} = \frac{r}{p} \sum_{k=r}^{\infty} \binom{k}{r} p^{r+1} (1-p)^{k-r} = \frac{r}{p}.$$

4.5.6 Let  $Y$  denote the number of trials to get the  $r$ th success, and let  $X$  denote the number of trials in excess of  $r$  to get the  $r$ th success. Then  $X = Y - r$ . Substituting into Theorem 4.5.1 gives

$$p_X(k) = \binom{k+r-1}{r-1} p^r (1-p)^k = \binom{k+r-1}{k} p^r (1-p)^k, \quad k = 0, 1, 2, \dots$$

4.5.7 Here  $X = Y - r$ , where  $Y$  has the negative binomial distribution as described in Theorem 4.5.1. Using the properties (1), (2), and (3) given by the theorem, we can write  $E(X) = E(Y - r) =$

$$E(Y) - E(r) = \frac{r}{p} - r = \frac{r(1-p)}{p} \quad \text{and} \quad \text{Var}(X) = \text{Var}(Y - r) = \text{Var}(Y) + \text{Var}(r) =$$

$$\frac{r(1-p)}{p^2} + 0 = \frac{r(1-p)}{p^2}.$$

$$\text{Also, } M_X(t) = M_{Y-r}(t) = e^{-rt} M_Y(t) = e^{-rt} \left[ \frac{pe^t}{1-(1-p)e^t} \right]^r = \left[ \frac{p}{1-(1-p)e^t} \right]^r.$$

4.5.8 For each  $X_i$ ,  $M_{X_i}(t) = \left[ \frac{(4/5)e^t}{1-(1-4/5)e^t} \right]^3$ ,  $i = 1, 2, 3$ . If  $X = X_1 + X_2 + X_3$ , it follows that

$$M_X(t) = \prod_{i=1}^3 M_{X_i}(t) = \left[ \frac{(4/5)e^t}{1-(1-4/5)e^t} \right]^9, \quad \text{which implies that } p_X(k) = \binom{k-1}{8} \left( \frac{4}{5} \right)^9 \left( \frac{1}{5} \right)^{k-9},$$

$$k = 9, 10, \dots \quad \text{Then } P(10 \leq X \leq 12) = \sum_{k=10}^{12} p_X(k) = 0.66.$$

$$4.5.9 \quad M_X^{(1)}(t) = r \left[ \frac{pe^t}{1-(1-p)e^t} \right]^{r-1} [pe^t[1-(1-p)e^t]^{-2}(1-p)e^t + [1-(1-p)e^t]^{-1}pe^t]. \quad \text{When } t = 0,$$

$$M_X^{(1)}(0) = E(X) = r \left[ \frac{p(1-p)}{p^2} + \frac{p}{p} \right] = \frac{r}{p}.$$

$$4.5.10 \quad M_X(t) = \prod_{i=1}^k M_{X_i}(t) = \prod_{i=1}^k \left[ \frac{pe^t}{1-(1-p)e^t} \right]^{r_i} = \left[ \frac{pe^t}{1-(1-p)e^t} \right]^{r^*}, \quad \text{where } r^* = \sum_{i=1}^k r_i. \quad \text{Also, } E(X) =$$

$$E(X_1 + X_2 + \dots + X_k) = E(X_1) + E(X_2) + \dots + E(X_k) = \sum_{i=1}^k \frac{r_i}{p} = \frac{r^*}{p} \quad \text{and} \quad \text{Var}(X) =$$

$$\sum_{i=1}^k \text{Var}(X_i) = \sum_{i=1}^k \frac{r_i(1-p)}{p^2} = \frac{r^*(1-p)}{p^2}.$$

## Section 4.6: The Gamma Distribution

**4.6.1** Let  $Y_i$  = lifetime of  $i$ th gauge,  $i = 1, 2, 3$ . By assumption,  $f_{Y_i}(y) = 0.001e^{-0.001y}$ ,  $y > 0$ . Define the random variable  $Y = Y_1 + Y_2 + Y_3$  to be the lifetime of the system.

By Theorem 4.6.1,  $f_Y(y) = \frac{(0.001)^3}{2} y^2 e^{-0.001y}$ ,  $y > 0$ .

**4.6.2** The time until the 24<sup>th</sup> breakdown is a gamma random variable with parameters  $r = 24$  and  $\lambda = 3$ . The mean of this random variable is  $r/\lambda = 24/3 = 8$  months.

**4.6.3** If  $E(Y) = \frac{r}{\lambda} = 1.5$  and  $\text{Var}(Y) = \frac{r}{\lambda^2} = 0.75$ , then  $r = 3$  and  $\lambda = 2$ , which makes  $f_Y(y) = 4y^2 e^{-2y}$ ,  $y > 0$ . Then  $P(1.0 \leq Y_i \leq 2.5) = \int_{1.0}^{2.5} 4y^2 e^{-2y} dy = 0.55$ . Let  $X$  = number of  $Y_i$ 's in the interval  $(1.0, 2.5)$ . Since  $X$  is a binomial random variable with  $n = 100$  and  $p = 0.55$ ,  $E(X) = np = 55$ .

**4.6.4** 
$$f_{\lambda Y}(y) = \frac{1}{\lambda} f_Y(y/\lambda) = \frac{1}{\lambda} \frac{\lambda^r}{\Gamma(r)} \left(\frac{y}{\lambda}\right)^{r-1} e^{-\lambda(y/\lambda)} = \frac{1}{\Gamma(r)} y^{r-1} e^{-y}$$

**4.6.5** To find the maximum of the function  $f_Y(y) = \frac{\lambda^r}{\Gamma(r)} y^{r-1} e^{-\lambda y}$ , differentiate it with respect to  $y$  and set it equal to 0; that is  $\frac{df_Y(y)}{dy} = \frac{d}{dy} \frac{\lambda^r}{\Gamma(r)} y^{r-1} e^{-\lambda y} = \frac{\lambda^r}{\Gamma(r)} [(r-1)y^{r-2} e^{-\lambda y} - \lambda y^{r-1} e^{-\lambda y}] = 0$ . This implies  $\frac{\lambda^r}{\Gamma(r)} y^{r-2} e^{-\lambda y} [(r-1) - \lambda y] = 0$ , whose solution is  $y_{\text{mode}} = \frac{r-1}{\lambda}$ . Since the derivative is positive for  $y < y_{\text{mode}}$ , and negative for  $y > y_{\text{mode}}$ , then there is a maximum.

**4.6.6** Let  $Z$  be a standard normal random variable. Then  $E(Z^2) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} z^2 e^{-z^2/2} dz = \sqrt{\frac{2}{\pi}} \int_0^{\infty} z^2 e^{-z^2/2} dz = 1$ . Let  $y = z^2$ . Then  $E(Z^2) = \frac{2}{\sqrt{\pi}} \Gamma\left(1 + \frac{1}{2}\right) = \frac{2}{\sqrt{\pi}} \left(\frac{1}{2}\right) \Gamma\left(\frac{1}{2}\right)$ , which implies that  $\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$ .

**4.6.7**  $\Gamma\left(\frac{7}{2}\right) = \frac{5}{2} \Gamma\left(\frac{5}{2}\right) = \frac{5}{2} \frac{3}{2} \Gamma\left(\frac{3}{2}\right) = \frac{5}{2} \frac{3}{2} \frac{1}{2} \Gamma\left(\frac{1}{2}\right) = \frac{15}{8} \Gamma\left(\frac{1}{2}\right)$  by Theorem 4.6.2, part 2. Further,  $\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$  by Question 4.6.6.

**4.6.8** 
$$E(Y^m) = \int_0^{\infty} y^m \cdot \frac{\lambda^r}{(r-1)!} y^{r-1} e^{-\lambda y} dy = \int_0^{\infty} \frac{\lambda^r}{(r-1)!} y^{m+r-1} e^{-\lambda y} dy = \frac{(m+r-1)!}{\lambda^m (r-1)!} \int_0^{\infty} \frac{\lambda^{m+r}}{(m+r-1)!} y^{m+r-1} e^{-\lambda y} dy = \frac{(m+r-1)!}{\lambda^m (r-1)!}.$$

**4.6.9** Write the gamma moment-generating function in the form  $M_Y(t) = (1 - t/\lambda)^{-r}$ .

Then  $M_Y^{(1)}(t) = -r(1 - t/\lambda)^{-r-1}(-1/\lambda) = (r/\lambda)(1 - t/\lambda)^{-r-1}$  and  $M_Y^{(2)}(t) = (r/\lambda)(-r-1)(1 - t/\lambda)^{-r-2} \cdot (-1/\lambda) = (r/\lambda^2)(r+1)(1 - t/\lambda)^{-r-2}$ .

Therefore,  $E(Y) = M_Y^{(1)}(0) = \frac{r}{\lambda}$  and  $\text{Var}(Y) = M_Y^{(2)}(0) - [M_Y^{(1)}(0)]^2 = \frac{r(r+1)}{\lambda^2} - \frac{r^2}{\lambda^2} = \frac{r}{\lambda^2}$ .

**4.6.10**  $M_Y(t) = (1 - t/\lambda)^{-r}$  so  $M_Y^{(1)}(t) = \frac{d}{dt}(1 - t/\lambda)^{-r} = r(1 - t/\lambda)^{-r-1}(-1/\lambda) = \frac{r}{\lambda}(1 - t/\lambda)^{-r-1}$  and

$$M_Y^{(2)}(t) = \frac{d}{dt} \frac{r}{\lambda} (1 - t/\lambda)^{-r-1} = \frac{r}{\lambda} (-r-1)(1 - t/\lambda)^{-r-2}(-1/\lambda) = \frac{r(r+1)}{\lambda^2} (1 - t/\lambda)^{-r-2}$$

For an arbitrary integer  $m \geq 2$ , we can generalize the above to see that

$$M_Y^{(m)}(t) = \frac{r(r+1)\dots(r+m-1)}{\lambda^m} (1 - t/\lambda)^{-r-m}. \text{ Then } E(Y^m) = M_Y^{(m)}(0) = \frac{r(r+1)\dots(r+m-1)}{\lambda^m}.$$

But note that  $\frac{r(r+1)\dots(r+m-1)}{\lambda^m} = \frac{\Gamma(r+m)}{\Gamma(r)\lambda^m}$ . The right hand side of the equation is equal to the expression in Question 4.6.8 when  $r$  is an integer.

## Chapter 5: Estimation

### Section 5.2: Estimating Parameters: The Method of Maximum Likelihood and the Method of Moments

$$5.2.1 \quad L(\theta) = \prod_{i=1}^8 \theta^{k_i} (1-\theta)^{1-k_i} = \theta^{\sum_{i=1}^8 k_i} (1-\theta)^{8-\sum_{i=1}^8 k_i} = \theta^5 (1-\theta)^3$$

$$\frac{dL(\theta)}{d\theta} = \theta^5 3(1-\theta)^2(-1) + 5\theta^4(1-\theta)^3 = \theta^4(1-\theta)^2(-8\theta+5) \cdot \frac{dL(\theta)}{d\theta} = 0 \text{ implies } \theta_e = 5/8$$

$$5.2.2 \quad L(p) = p(1-p)(1-p)p(1-p) = p^2(1-p)^3$$

$$L(1/3) = \left(\frac{1}{3}\right)^2 \left(\frac{2}{3}\right)^3 = \frac{8}{243} \text{ is greater than } L(1/2) = \left(\frac{1}{2}\right)^5 = \frac{1}{32}, \text{ so } p_e = 1/3.$$

$$5.2.3 \quad L(\theta) = \prod_{i=1}^4 \lambda e^{-\lambda y_i} = \lambda^4 e^{-\lambda \sum_{i=1}^4 y_i} = \lambda^4 e^{-32.8\lambda}.$$

$$\frac{dL(\lambda)}{d\lambda} = \lambda^4(-32.8)e^{-32.8\lambda} + 4\lambda^3 e^{-32.8\lambda} = \lambda^3 e^{-32.8\lambda}(4 - 32.8\lambda)$$

$$\frac{dL(\lambda)}{d\lambda} = 0 \text{ implies } \lambda_e = 4/32.8 = 0.122$$

$$5.2.4 \quad L(\theta) = \prod_{i=1}^n \frac{\theta^{2k_i} e^{-\theta^2}}{k_i!} = \frac{\theta^{2\sum_{i=1}^n k_i} e^{-n\theta^2}}{\prod_{i=1}^n k_i!}.$$

$$\ln L(\theta) = \left(2\sum_{i=1}^n k_i\right)(\ln \theta) - n\theta^2 + \ln \prod_{i=1}^n k_i!$$

$$\frac{d \ln L(\theta)}{d\theta} = 0 \text{ implies } \frac{2\sum_{i=1}^n k_i}{\theta} - 2n\theta = \frac{2\sum_{i=1}^n k_i - 2n\theta^2}{\theta} = 0 \text{ or } \theta_e = \sqrt{\frac{\sum_{i=1}^n k_i}{n}}$$

$$5.2.5 \quad L(\theta) = \prod_{i=1}^3 \frac{y_i^3 e^{-y_i/\theta}}{6\theta^4} = \frac{\left(\prod_{i=1}^3 y_i^3\right) e^{-\sum_{i=1}^3 y_i/\theta}}{216\theta^{12}}.$$

$$\ln L(\theta) = \ln \prod_{i=1}^3 y_i^3 - \frac{1}{\theta} \sum_{i=1}^3 y_i - \ln 216 - 12 \ln \theta$$

$$\frac{d \ln L(\theta)}{d\theta} = \frac{1}{\theta^2} \sum_{i=1}^3 y_i - \frac{12}{\theta} = \frac{\sum_{i=1}^3 y_i - 12\theta}{\theta^2}$$

$$\frac{d \ln L(\theta)}{d\theta} = 0 \text{ implies } \frac{\sum_{i=1}^3 y_i - 12\theta}{\theta^2} = \frac{8.8 - 12\theta}{\theta^2} = 0 \text{ or } \theta_e = 0.733$$

$$5.2.6 \quad L(\theta) = \prod_{i=1}^4 \frac{\theta}{2\sqrt{y_i}} e^{-\theta\sqrt{y_i}} = \frac{\theta^4}{16 \prod_{i=1}^4 \sqrt{y_i}} e^{-\theta \sum_{i=1}^4 \sqrt{y_i}}$$

$$\ln L(\theta) = 4 \ln \theta - \ln \left( 16 \prod_{i=1}^4 \sqrt{y_i} \right) - \theta \sum_{i=1}^4 \sqrt{y_i}$$

$$\frac{d \ln L(\theta)}{d\theta} = \frac{4}{\theta} - \sum_{i=1}^4 \sqrt{y_i}.$$

$$\frac{d \ln L(\theta)}{d\theta} = 0 \text{ implies } \theta_e = \frac{4}{\sum_{i=1}^4 \sqrt{y_i}} = \frac{4}{8.766} = 0.456$$

$$5.2.7 \quad L(\theta) = \prod_{i=1}^5 \theta y_i^{\theta-1} = \theta^5 \left( \prod_{i=1}^5 y_i \right)^{\theta-1}.$$

$$\ln L(\theta) = 5 \ln \theta + (\theta - 1) \sum_{i=1}^5 \ln y_i$$

$$\frac{d \ln L(\theta)}{d\theta} = \frac{5}{\theta} + \sum_{i=1}^5 \ln y_i = \frac{5 + \theta \sum_{i=1}^5 \ln y_i}{\theta}$$

$$\frac{d \ln L(\theta)}{d\theta} = 0 \text{ implies } \frac{5 - 0.625\theta}{\theta} = 0 \text{ or } \theta_e = 8.00$$

$$\frac{d \ln L(\theta)}{d\theta} = 0 \text{ implies } \frac{5 - 0.625\theta}{\theta} = 0 \text{ or } \theta_e = 8.00$$

$$5.2.8 \quad L(p) = \prod_{i=1}^n (1-p)^{k_i-1} p = (1-p)^{\sum_{i=1}^n k_i - n} p^n$$

$$\ln L(p) = \left( \sum_{i=1}^n k_i - n \right) \ln(1-p) + n \ln p$$

$$\frac{\ln L(p)}{dp} = -\frac{\sum_{i=1}^n k_i - n}{1-p} + \frac{n}{p} \text{ and } \frac{\ln L(p)}{dp} = 0 \text{ implies } p_e = \frac{n}{\sum_{i=1}^n k_i}$$

For the data,  $n = 1011$ , and  $\sum_{i=1}^n k_i = 1(678) + 2(227) + 3(56) + 4(28) + 5(8) + 6(14) = 1536$ ,

so  $p_e = \frac{1011}{1536} = 0.658$ . The table gives the comparison of observed and expected frequencies.

5.2.9

(a)			
	No. of Occupants	Observed Frequency	Expected Frequency
	1	678	665.2
	2	227	227.5
	3	56	77.8
	4	28	26.6
	5	8	9.1
	6	14	3.1

From the Comment following Example 5.2.1,

$$\lambda_e = \frac{1}{n} \sum_{i=1}^n k_i = \frac{1}{59} [1(19) + 2(12) + 3(13) + 4(9)] = 2.00.$$

- (b) For example, the expected frequency for the  $k = 2$  class is  $59 \cdot e^{-2} \frac{2^3}{3!} = 10.6$

The full set of expected values is given in column of the following table.

No. of No-hitters	Observed Frequency	Expected Frequency
0	6	8.0
1	19	16.0
2	12	16.0
3	13	10.6
4	9	8.4

The last expected frequency has been chosen to make that column sum to  $n = 59$ .

The techniques to be introduced in Chapter 10 would support the Poisson model. The difference between observed and expected frequencies is in part because the game of baseball changed significantly over the years from 1950 to 2008. Thus, the parameter  $\lambda$  would not be constant over this period.

- 5.2.10** (a)  $L(\theta) = \left(\frac{1}{\theta}\right)^n$ , if  $0 \leq y_1, y_2, \dots, y_n \leq \theta$ , and 0 otherwise. Thus  $\theta_e = y_{\max}$ , which for these data is 14.2.

- (b)  $L(\theta) = \left(\frac{1}{\theta_2 - \theta_1}\right)^n$ , if  $\theta_1 \leq y_1, y_2, \dots, y_n \leq \theta_2$ , and 0 otherwise. Thus  $\theta_{1e} = y_{\min}$  and  $\theta_{2e} = y_{\max}$ . For these data,  $\theta_{1e} = 1.8$ ,  $\theta_{2e} = 14.2$ .

- 5.2.11**  $L(\theta) = \prod_{i=1}^6 \frac{2y_i}{1-\theta^2} = \frac{64 \prod_{i=1}^6 y_i}{(1-\theta^2)^6}$ , if  $\theta \leq y_1, y_2, \dots, y_n \leq 1$  and 0 otherwise. If  $\theta > y_{\min}$ , then  $L(\theta) = 0$ .

So  $\theta_e \leq y_{\min}$ . Also, to maximize  $L(\theta)$ , minimize the denominator, which in turn means maximize  $\theta$ . Thus  $\theta_e \geq y_{\min}$ . We conclude that  $\theta_e = y_{\min}$ , which for these data is 0.21.

$$5.2.12 \quad L(\theta) = \prod_{i=1}^n \frac{2y_i}{\theta^2} = 2^n \left( \prod_{i=1}^n y_i \right) \theta^{-2n}, \text{ if } 0 \leq y_1, y_2, \dots, y_n \leq \theta, \text{ and } 0 \text{ otherwise. To maximize } L(\theta)$$

maximize  $\theta$ . Since each  $y_i \leq \theta$  for  $1 \leq i \leq n$ , the maximum value for  $\theta$  under these constraints is the maximum of the  $y_i$ , or  $\theta_e = y_{\max}$ .

$$5.2.13 \quad L(\theta) = \prod_{i=1}^{25} \theta k^\theta \left( \frac{1}{y_i} \right)^{\theta+1} = \theta^{25} k^{25\theta} \left( 1 / \prod_{i=1}^{25} y_i \right)^{\theta+1}, y_i \geq k, 1 \leq i \leq 25$$

$$\ln L(\theta) = 25 \ln \theta + 25\theta \ln k - (\theta + 1) \sum_{i=1}^n \ln y_i$$

$$\frac{d \ln L(\theta)}{d\theta} = \frac{25}{\theta} + 25 \ln k - \sum_{i=1}^n \ln y_i, \text{ so } \theta_e = \frac{25}{-25 \ln k + \sum_{i=1}^n \ln y_i}$$

$$5.2.14 \quad L(p) = \prod_{i=1}^n \binom{k_i + r - 1}{k_i} (1-p)^{k_i} p^r$$

$$\ln L(p) = \ln \prod_{k=1}^n \binom{k + r - 1}{k} + \left( \sum_{k=1}^n k_i \right) \ln(1-p) + nr \ln p$$

$$\frac{\partial \ln L(p)}{\partial p} = 0 - \frac{\sum_{i=1}^n k_i}{1-p} + \frac{nr}{p}$$

$$\text{Setting } \frac{\partial \ln L(p)}{\partial p} = 0 \text{ gives } p_e = \frac{1}{\frac{1}{\bar{k}} + 1} = \frac{r}{\bar{k} + r}$$

Note that  $\frac{\partial^2 \ln L(p)}{\partial p^2} < 0$ , so a maximum does occur.

$$5.2.15 \quad L(\alpha, \beta) = \prod_{i=1}^n \alpha \beta y_i^{\beta-1} e^{-\alpha y_i^\beta} = \alpha^n \beta^n \left( \prod_{i=1}^n y_i \right)^{\beta-1} e^{-\alpha \sum_{i=1}^n y_i^\beta}$$

$$\ln L(\alpha, \beta) = n \ln \alpha + n \ln \beta + (\beta - 1) \ln \left( \prod_{i=1}^n y_i \right) - \alpha \sum_{i=1}^n y_i^\beta$$

$$\frac{\partial \ln L(\alpha, \beta)}{\partial \alpha} = \frac{n}{\alpha} - \sum_{i=1}^n y_i^\beta$$

$$\text{Setting } \frac{\partial \ln L(\alpha, \beta)}{\partial \alpha} = 0 \text{ gives } \alpha_e = \frac{n}{\sum_{i=1}^n y_i^\beta}$$

**5.2.16** Let  $\theta = \sigma^2$ , so  $L(\theta) = \prod_{i=1}^n \frac{1}{\sqrt{2\pi\theta}} e^{-\frac{1}{2} \frac{(y_i - \mu)^2}{\theta}} = 2\pi^{-n/2} \theta^{-n/2} e^{-\frac{1}{2\theta} \sum_{i=1}^n (y_i - \mu)^2}$

$$\ln L(\theta) = -\frac{n}{2} \ln 2\pi - \frac{n}{2} \ln \theta - \frac{1}{2} \frac{1}{\theta} \sum_{i=1}^n (y_i - \mu)^2$$

$$\frac{d \ln L(\theta)}{d\theta} = -\frac{n}{2\theta} + \frac{1}{2} \frac{1}{\theta^2} \sum_{i=1}^n (y_i - \mu)^2 = \frac{1}{2} \frac{-n\theta + \sum_{i=1}^n (y_i - \mu)^2}{\theta^2}$$

$$\text{Setting } \frac{d \ln L(\theta)}{d\theta} = 0 \text{ gives } \theta_e = \sigma_e^2 = \frac{1}{n} \sum_{i=1}^n (y_i - \mu)^2$$

**5.2.17**  $E(Y) = \int_0^\theta y \frac{2y}{\theta^2} dy = \frac{2y^3}{3\theta^2} \Big|_0^\theta = \frac{2}{3} \theta$ . Setting  $\frac{2}{3} \theta = \bar{y}$  gives  $\theta_e = \frac{3}{2} \bar{y} = 75$ . The maximum likelihood estimate is  $y_{\max} = 92$ .

**5.2.18**  $E(Y) = \int_0^1 y(\theta^2 + \theta)y^{\theta-1}(1-y)dy = (\theta^2 + \theta) \int_0^1 y^\theta(1-y)dy = \frac{\theta}{\theta+2}$ . Set  $\frac{\theta}{\theta+2} = \bar{y}$ , which yields  $\theta_e = \frac{2\bar{y}}{1-\bar{y}}$

**5.2.19** For  $Y$  Poisson,  $E(Y) = \lambda$ . Then  $\lambda_e = \bar{y} = 13/6$ . The maximum likelihood estimate is the same.

**5.2.20** For  $Y$  exponential,  $E(Y) = 1/\lambda$ . Then  $1/\lambda = \bar{y}$  implies  $\lambda_e = 1/\bar{y}$ .

$$5.2.21 \quad E(Y) = \theta_1 \text{ so } \theta_{1e} = \bar{y}.$$

$$E(Y^2) = \int_{\theta_1 - \theta_2}^{\theta_1 + \theta_2} y^2 \frac{1}{2\theta_2} dy = \frac{1}{2\theta_2} \left[ \frac{y^3}{3} \right]_{\theta_1 - \theta_2}^{\theta_1 + \theta_2} = \theta_1^2 + \frac{1}{3}\theta_2^2$$

Substitute  $\theta_{1e} = \bar{y}$  into the equation  $\theta_1^2 + \frac{1}{3}\theta_2^2 = \frac{1}{n} \sum_{i=1}^n y_i^2$  to obtain  $\theta_{2e} = \sqrt{3 \left( \frac{1}{n} \sum_{i=1}^n y_i^2 - \bar{y}^2 \right)}$ .

$$5.2.22 \quad E(Y) = \int_k^\infty y \theta k^\theta \left( \frac{1}{y_i} \right)^{\theta+1} dy = \theta k^\theta \int_k^\infty y^{-\theta} dy = \frac{\theta k}{\theta - 1}$$

Setting  $\frac{\theta k}{\theta - 1} = \bar{y}$  gives  $\theta_e = \bar{y} / (\bar{y} - k)$

$$5.2.23 \quad E(X) = 0 \cdot \theta(1 - \theta)^{1-0} + 1 \cdot \theta(1 - \theta)^{1-1} = \theta.$$

Then  $\theta_e = \bar{y}$ , which for the given data is 2/5.

$$5.2.24 \quad E(Y) = \mu, \text{ so } \mu_e = \bar{y}. \quad E(Y^2) = \sigma^2 + \mu^2. \quad \text{Then substitute } \mu_e = \bar{y} \text{ into the equation for } E(Y^2) \text{ to}$$

obtain  $\sigma_e^2 + \bar{y}^2 = \frac{1}{n} \sum_{i=1}^n y_i^2$  or  $\sigma_e^2 = \frac{1}{n} \sum_{i=1}^n y_i^2 - \bar{y}^2$

$$5.2.25 \quad \text{From Theorem 4.6.3, } E(Y) = \frac{r}{\lambda}. \quad \text{Var}(Y) = \frac{r}{\lambda^2}.$$

$$\text{Then } E(Y^2) = \text{Var}(Y) + E(Y)^2 = \frac{r}{\lambda^2} + \left( \frac{r}{\lambda} \right)^2 = \frac{r(r+1)}{\lambda^2}$$

Set  $\frac{r}{\lambda} = \frac{1}{n} \sum_{i=1}^n y_i$  to obtain  $r = \frac{\lambda}{n} \sum_{i=1}^n y_i$ . Substitute that value for  $r$  in the equation

$\frac{r(r+1)}{\lambda^2} = \frac{1}{n} \sum_{i=1}^n y_i^2$ . With this substitution, the method of moments estimate for  $\lambda$  is

$$\lambda_e = \frac{\sum_{i=1}^n y_i}{\sum_{i=1}^n y_i^2 - \frac{1}{n} \left( \sum_{i=1}^n y_i \right)^2} = \frac{\bar{y}}{\frac{1}{n} \sum_{i=1}^n y_i^2 - \bar{y}^2}. \quad \text{Then } r_e = \frac{\lambda_e}{n} \sum_{i=1}^n y_i = \bar{y} \lambda_e$$

**5.2.26** From Chapter 4,  $E(X) = 1/p$ . Setting  $1/p = \bar{x}$ , gives  $p_e = \frac{1}{\bar{x}}$ . For the given data,  $p_e = 0.479$ . The expected frequencies are:

No. of clusters/song	Observed frequency	Expected frequency
1	132	119.8
2	52	62.4
3	34	32.5
4	9	16.9
5	7	8.8
6	5	4.6
7	5	2.4
$\geq 8$	6	2.6

The last expected frequency has been chosen to make that column sum to  $n = 250$ .

**5.2.27**  $\text{Var}(Y) = \hat{\sigma}^2$  implies  $E(Y^2) - E(Y)^2 = \frac{1}{n} \sum_{i=1}^n y_i^2 - \bar{y}^2$ . However by the first given equation,  $E(Y^2) = \bar{y}^2$ . Removing these equal terms from the equation above gives the second equation of Definition 5.2.3, or  $E(Y^2) = \frac{1}{n} \sum_{i=1}^n y_i^2$ .

## Section 5.3: Interval Estimation

**5.3.1** The confidence interval is  $\left( \bar{y} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{y} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right)$

$$= \left( 107.9 - 1.96 \frac{15}{\sqrt{50}}, 107.9 + 1.96 \frac{15}{\sqrt{50}} \right) = (103.7, 112.1).$$

**5.3.2** The confidence interval is  $\left( \bar{y} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{y} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right)$

$$= \left( 0.766 - 1.96 \frac{0.09}{\sqrt{19}}, 0.766 + 1.96 \frac{0.09}{\sqrt{19}} \right) = (0.726, 0.806). \text{ The value of } 0.80 \text{ is believable.}$$

**5.3.3** The confidence interval is  $\left( \bar{y} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{y} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right)$

$$= \left( 70.833 - 1.96 \frac{8.0}{\sqrt{6}}, 70.833 + 1.96 \frac{8.0}{\sqrt{6}} \right) = (64.432, 77.234). \text{ Since } 80 \text{ does not fall within}$$

the confidence interval, that men and women metabolize methylmercury at the same rate is not believable.

**5.3.4** The confidence interval is  $\left( \bar{y} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{y} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right)$

$$= \left( 188.4 - 1.96 \frac{40.7}{\sqrt{38}}, 188.4 + 1.96 \frac{40.7}{\sqrt{38}} \right) = (175.46, 201.34). \text{ Since } 192 \text{ does fall in the}$$

confidence interval, there is doubt the diet has an effect.

**5.3.5** The length of the confidence interval is  $2z_{\alpha/2} \frac{\sigma}{\sqrt{n}} = \frac{2(1.96)(14.3)}{\sqrt{n}} = \frac{56.056}{\sqrt{n}}.$

For  $\frac{56.056}{\sqrt{n}} \leq 3.06, n \geq \left( \frac{56.056}{3.06} \right)^2 = 335.58, \text{ so take } n = 336.$

**5.3.6** (a)  $P(-1.64 < Z < 2.33) = 0.94$ , a 94% confidence level.

(b)  $P(-\infty < Z < 2.58) = 0.995$ , a 99.5% confidence level.

(c)  $P(-1.64 < Z < 0) = 0.45$ , a 45% confidence level.

**5.3.7** The probability that the given interval will contain  $\mu$  is  $P(-0.96 < Z < 1.06) = 0.6869$ .  
The probability of four or five such intervals is binomial with  $n = 5$  and  $p = 0.6869$ , so the probability is  $5(0.6869)^4(0.3131) + (0.6869)^5 = 0.501$ .

**5.3.8** The given interval is symmetric about  $\bar{y}$ .

**5.3.9** The interval given is correctly *calculated*. However, the data do not appear to be normal, so claiming that it is a 95% confidence interval would not be correct.

$$\begin{aligned} \mathbf{5.3.10} \quad & \left( \frac{192}{540} - 1.96 \sqrt{\frac{(192/540)(1-192/540)}{540}}, \frac{192}{540} + 1.96 \sqrt{\frac{(192/540)(1-192/540)}{540}} \right) \\ & = (0.316, 0.396) \end{aligned}$$

**5.3.11** Let  $p$  be the probability that a viewer would watch less than a quarter of the advertisements during Super Bowl XXIX. The confidence interval for  $p$  is

$$\begin{aligned} & \left( \frac{281}{1015} - 1.64 \sqrt{\frac{(281/1015)(1-281/1015)}{1015}}, \frac{281}{1015} + 1.64 \sqrt{\frac{(281/1015)(1-281/1015)}{1015}} \right) \\ & = (0.254, 0.300) \end{aligned}$$

**5.3.12** Budweiser would use the sample proportion 0.54 alone as the estimate. Schlitz would construct the 95% confidence interval (0.36, 0.56) to claim that values  $< 0.50$  are believable.

**5.3.13** In closest integer to  $0.63(2253)$  is 1419. This gives the confidence interval

$$\begin{aligned} & \left( \frac{1419}{2253} - 1.96 \sqrt{\frac{(1419/2253)(1-1419/2253)}{2253}}, \frac{1419}{2253} + 1.96 \sqrt{\frac{(1419/2253)(1-1419/2253)}{2253}} \right) \\ & = (0.610, 0.650). \text{ Since } 0.54 \text{ is not in the interval, the increase can be considered significant.} \end{aligned}$$

$$\mathbf{5.3.14} \quad \frac{k}{n} - 0.67 \sqrt{\frac{(k/n)(1-k/n)}{n}} = 0.57$$

$$\frac{k}{n} + 0.67 \sqrt{\frac{(k/n)(1-k/n)}{n}} = 0.63$$

Adding the two equations gives  $2\frac{k}{n} = 1.20$  or  $\frac{k}{n} = 0.60$

Substituting the value for  $\frac{k}{n}$  into the first equation above gives

$$0.60 - 0.67 \sqrt{\frac{(0.60)(1-0.60)}{n}} = 0.57. \text{ Solving this equation for } n \text{ gives } n = 120.$$

$$5.3.15 \quad 2.58\sqrt{\frac{p(1-p)}{n}} \leq 2.58\sqrt{\frac{1}{4n}} \leq 0.01, \text{ so take } n \geq \frac{(2.58)^2}{4(0.01)^2} = 16,641$$

5.3.16 For Foley to win the election, he needed to win at least 8088 of the absentee votes, since  $8088 > 8086 = 2174 + (14,000 - 8088)$ . If  $X$  is the number of absentee votes for Foley, then it is binomial with  $n = 14,000$  and  $p$  to be determined.

$$P(X \geq 8088) = P\left(\frac{X - 14,000p}{\sqrt{14,000p(1-p)}} \geq \frac{8088 - 14,000p}{\sqrt{14,000p(1-p)}}\right) = P\left(Z \geq \frac{8088 - 14,000p}{\sqrt{14,000p(1-p)}}\right).$$

For this probability to be 0.20,  $\frac{8088 - 14,000p}{\sqrt{14,000p(1-p)}} = z_{.20} = 0.84$ . This last equation can be solved by the quadratic formula or trial and error to obtain the approximate solution  $p = 0.5742$ .

5.3.17 Both intervals have confidence level approximately 50%.

5.3.18  $g(p) = p - p^2$ .  $g'(p) = 1 - 2p$ . Setting  $g'(p) = 0$  gives  $p = 1/2$ . Also,  $g''(p) = -2$ . Since the second derivative is negative at  $p = 1/2$ , a maximum occurs there. The maximum value of  $g(p)$  is  $g(1/2) = 1/4$ .

5.3.19 The margin of error is  $\frac{1.96}{2\sqrt{6224}} = 0.012$ . The 95% confidence interval is

$$\left( \frac{3921}{6224} - 1.96\sqrt{\frac{(3921/6224)(1 - 3921/6224)}{6224}}, \frac{3921}{6224} + 1.96\sqrt{\frac{(3921/6224)(1 - 3921/6224)}{6224}} \right)$$

$$= (0.618, 0.642)$$

5.3.20 From Definition 5.3.1,  $d = \frac{1.96}{2\sqrt{202}} = 0.069$ . The sample proportion is  $86/202 = 0.426$ . The largest believable value is  $0.426 + 0.069 = 0.495$ , so we should not accept the notion that the true proportion is as high as 50%.

**5.3.21** If  $X$  is hypergeometric, then  $\text{Var}(X/n) = \frac{p(1-p)}{n} \frac{N-n}{N-1}$ .

As before  $p(1-p) \leq 1/4$ . Thus, in Definition 5.3.1, substitute  $d = \frac{1.96}{2\sqrt{n}} \sqrt{\frac{N-n}{N-1}}$ .

**5.3.22** (a) The 90% confidence interval is

$$\left( \frac{126}{350} - 1.64 \sqrt{\frac{(126/350)(1-126/350)}{350}}, \frac{126}{350} + 1.64 \sqrt{\frac{(126/350)(1-126/350)}{350}} \right)$$

$$= (0.318, 0.402)$$

(b) Use for the margin of error  $1.64 \sqrt{\frac{(126/350)(1-126/350)}{350}} \sqrt{\frac{3000-350}{3000-1}}$   
 $= 0.039$ , which gives a confidence interval  $(0.321, 0.399)$

**5.3.23** If  $n$  is such that  $0.06 = \frac{1.96}{2\sqrt{n}}$ , then  $n$  is the smallest integer  $\geq \frac{1.96^2}{4(0.06)^2} = 266.8$ .

Take  $n = 267$ .

If  $n$  is such that  $0.03 = \frac{1.96}{2\sqrt{n}}$ , then  $n$  is the smallest integer  $\geq \frac{1.96^2}{4(0.03)^2} = 1067.1$ .

Take  $n = 1068$ .

**5.3.24** For candidate A, the believable values for the probability of winning fall in the range  $(0.52 - 0.05, 0.52 + 0.05) = (0.47, 0.57)$ . For candidate B, the believable values for the probability of winning fall in the range  $(0.48 - 0.05, 0.48 + 0.05) = (0.43, 0.53)$ . Since 0.50 falls in both intervals, there is a sense in which the candidates can be considered tied.

**5.3.25** Case 1:  $n$  is the smallest integer greater than  $\frac{z_{.02}^2}{4(0.05)^2} = \frac{2.05^2}{4(0.05)^2} = 420.25$ , so take  $n = 421$ .

Case 2:  $n$  is the smallest integer greater than  $\frac{z_{.04}^2}{4(0.04)^2} = \frac{1.75^2}{4(0.04)^2} = 478.5$ , so take  $n = 479$ .

**5.3.26** Take  $n$  to be the smallest integer  $\geq \frac{z_{.005}^2 p(1-p)}{(0.05)^2} = \frac{2.58^2 (0.40)(0.60)}{(0.05)^2} = 639.01$ , so  $n = 640$ .

**5.3.27** Take  $n$  to be the smallest integer  $\geq \frac{z_{.10}^2}{4(0.02)^2} = \frac{1.28^2}{4(0.02)^2} = 1024$ .

**5.3.28** (a) Take  $n$  to be the smallest integer  $\geq \frac{z_{.075}^2}{4(0.03)^2} = \frac{1.44^2}{4(0.03)^2} = 576$ .

(b) Take  $n$  to be the smallest integer  $\geq \frac{z_{.075}^2 p(1-p)}{(0.03)^2} = \frac{1.44^2 (0.10)(0.90)}{(0.03)^2} = 207.36$ ,

so let  $n = 208$ .

## Section 5.4: Properties of Estimators

**5.4.1**  $P(|\hat{\theta} - 3| > 1.0) = P(\hat{\theta} < 2) + P(\hat{\theta} > 4) =$   
 $P(\hat{\theta} = 1.5) + P(\hat{\theta} = 4.5) = P((1, 2)) + P((4, 5)) = 2 / 10$

**5.4.2** For the uniform variable  $Y$ ,  $F_Y(y) = \frac{y}{\theta}$ . By Theorem 3.10.1,

$$f_{\hat{\theta}}(y) = f_{Y_{\max}}(y) = n \frac{1}{\theta} \left( \frac{y}{\theta} \right)^{n-1} = n \frac{y^{n-1}}{\theta^n}$$

(a) For  $n = 6$  and  $\theta = 3$ ,

$$f_{\hat{\theta}}(y) = 6 \frac{1}{3} \left( \frac{y}{3} \right)^5 = \frac{2}{243} y^5 \quad P(|\hat{\theta} - 3| < 0.2) = \int_{2.8}^{3.2} \frac{2}{243} y^5 dy = \frac{2}{243} \frac{y^6}{6} \Big|_{2.8}^{3.2} = 0.812$$

(b) For  $n = 3$ ,

$$f_{\hat{\theta}}(y) = 3 \frac{1}{3} \left( \frac{y}{3} \right)^2 = \frac{1}{9} y^2 \quad P(|\hat{\theta} - 3| < 0.2) = \int_{2.8}^{3.2} \frac{1}{9} y^2 dy = \frac{1}{9} \frac{y^3}{3} \Big|_{2.8}^{3.2} = 0.401$$

**5.4.3**  $P(X < 250) = P\left(\frac{X - 500(0.52)}{\sqrt{500(0.52)(0.48)}} < \frac{250 - 500(0.52)}{\sqrt{500(0.52)(0.48)}}\right) = P(Z < -0.90) = 0.1841$

$$\begin{aligned}
 5.4.4 \quad P(19.0 < \bar{Y} < 21.0) &= P\left(\frac{19.0 - 20}{10/\sqrt{16}} < Z < \frac{21.0 - 20}{10/\sqrt{16}}\right) = P(-0.40 < Z < 0.40) = 0.6554 - 0.3446 \\
 &= 0.3108
 \end{aligned}$$

$$5.4.5 \quad (a) \quad E(\bar{X}) = E\left(\frac{1}{n} \sum_{i=1}^n X_i\right) = \frac{1}{n} \sum_{i=1}^n E(X_i) = \frac{1}{n} \sum_{i=1}^n \lambda = \lambda$$

(b) In general, the sample mean is an unbiased estimator of the mean  $\mu$ .

$$5.4.6 \quad f_{Y_{\min}}(y) = n \frac{1}{\theta} \left(1 - \frac{y}{\theta}\right)^{n-1}, \text{ so } E(Y_{\min}) = n \frac{1}{\theta} \int_0^{\theta} y \left(1 - \frac{y}{\theta}\right)^{n-1} dy$$

Integration by parts yields  $E(Y_{\min}) = \frac{\theta}{n+1}$ . An unbiased estimator would be  $(n+1)Y_{\min}$ .

$$5.4.7 \quad \text{First note that } F_Y(y) = 1 - e^{-(y-\theta)}, \quad \theta \leq y. \text{ By Theorem 3.10.1, } f_{Y_{\min}}(y) = ne^{-n(y-\theta)}, \quad \theta \leq y.$$

Then  $E(Y_{\min}) = \int_{\theta}^{\infty} y \cdot ne^{-n(y-\theta)} dy = \int_0^{\infty} (u + \theta) \cdot ne^{-nu} du$ , the last equality arising from the substitution  $u = y - \theta$ .

$$\text{Thus, } E(Y_{\min}) = \int_0^{\infty} (u + \theta) \cdot ne^{-nu} du = \int_0^{\infty} u \cdot ne^{-nu} du + \theta \int_0^{\infty} ne^{-nu} du = \frac{1}{n} + \theta.$$

$$\text{Finally, } E(Y_{\min} - \frac{1}{n}) = \frac{1}{n} + \theta - \frac{1}{n} = \theta.$$

$$5.4.8 \quad (a) \quad f_{Y'_3}(y) = 12 \left(\frac{y}{\theta}\right)^2 \left(1 - \frac{y}{\theta}\right) \frac{1}{\theta} = \frac{12}{\theta^4} [y^2(\theta - y)]$$

$$E(Y'_3) = \frac{3}{5}\theta, \text{ so the unbiased estimator is } \frac{5}{3}Y'_3.$$

$$(b) \quad \frac{5}{3}Y'_3 = \frac{5}{3}18 = 30$$

(c) Suppose the sample were 10, 14, 18, 31. The estimate for  $\theta$  is 30, but the largest observation 31 falls outside of the  $[0, 30]$  interval.

$$5.4.9 \quad E(Y) = 2 \int_0^{1/\theta} y^2 \theta^2 dy = \frac{2}{3} \left( \frac{1}{\theta} \right).$$

$$E[c(Y_1 + 2Y_2)] = c[E(Y_1) + 2E(Y_2)] = c \left[ \frac{2}{3} \left( \frac{1}{\theta} \right) + \frac{4}{3} \left( \frac{1}{\theta} \right) \right] = 2c \left( \frac{1}{\theta} \right).$$

For the estimator to be unbiased,  $2c = 1$  or  $c = 1/2$ .

$$5.4.10 \quad E(Y^2) = \int_0^\theta y^2 \frac{1}{\theta} dy = \frac{\theta^2}{3}, \text{ so } 3Y^2 \text{ is unbiased.}$$

5.4.11  $E(W^2) = \text{Var}(W) + E(W)^2 = \text{Var}(W) + \theta^2$ . Thus,  $W^2$  is unbiased only if  $\text{Var}(W) = 0$ , which in essence means that  $W$  is constant.

5.4.12 For each  $i$ ,  $E[(Y_i - \mu)^2] = \sigma^2$  by definition of  $\sigma^2$ .

$$E \left[ \frac{1}{n} \sum_{i=1}^n (Y_i - \mu)^2 \right] = \frac{1}{n} \sum_{i=1}^n E[(Y_i - \mu)^2] = \frac{1}{n} n \sigma^2 = \sigma^2$$

$$5.4.13 \quad f_{\frac{n+1}{n} Y_{\max}}(y) = \frac{n}{n+1} f_{Y_{\max}} \left( \frac{n}{n+1} y \right) = \frac{n}{n+1} \frac{n}{\theta} \frac{n^{n-1}}{(n+1)^{n-1}} \frac{y^{n-1}}{\theta^{n-1}} = \frac{n^{n+1}}{(n+1)^n} \frac{y^{n-1}}{\theta^n}$$

The median of this distribution is the number  $m$  such that  $1/2 =$

$$\int_0^m \frac{n^{n+1}}{(n+1)^n} \frac{y^{n-1}}{\theta^n} dy = \frac{n^n}{(n+1)^n} \frac{y^n}{\theta^n} \Big|_0^m = \frac{n^n}{(n+1)^n} \frac{m^n}{\theta^n}$$

Solving for  $m$  gives  $m = \frac{1}{\sqrt[n]{2}} \frac{(n+1)}{n} \theta$ . The estimator is unbiased only when  $n = 1$ .

$$5.4.14 \quad f_{Y_{\min}}(y) = n f_Y(y) (1 - F_Y(y))^{n-1} = n \frac{1}{\theta} e^{-y/\theta} [1 - (1 - e^{-y/\theta})]^{n-1} = n \frac{1}{\theta} e^{-ny/\theta}.$$

Then  $f_{nY_{\min}}(y) = \frac{1}{n} f_{Y_{\min}} \left( \frac{y}{n} \right) = \frac{1}{n} n \frac{1}{\theta} e^{-\frac{y}{n}/\theta} = \frac{1}{\theta} e^{-y/\theta}$ .  $E(nY_{\min}) = \theta$ , so  $nY_{\min}$  is unbiased.

Also, the sample mean  $\frac{1}{n} \sum_{i=1}^n Y_i$  is unbiased (see Question 5.4.5).

$$5.4.15 \quad E(\bar{W}^2) = \text{Var}(\bar{W}) + E(\bar{W})^2 = \frac{\sigma^2}{n} + \mu^2, \text{ so } \lim_{n \rightarrow \infty} E(\bar{W}^2) = \lim_{n \rightarrow \infty} \left( \frac{\sigma^2}{n} + \mu^2 \right) = \mu^2$$

$$5.4.16 \quad \hat{\theta}_n = \frac{1}{n} \sum_{i=1}^n (Y_i - \bar{Y})^2, \text{ so } E(\hat{\theta}_n) = \frac{n-1}{n} \sigma^2. \text{ This estimator is asymptotically unbiased since}$$

$$\lim_{n \rightarrow \infty} E(\hat{\theta}_n) = \lim_{n \rightarrow \infty} \frac{n-1}{n} \sigma^2 = \sigma^2.$$

$$5.4.17 \quad \text{a) } E(\hat{p}_1) = E(X_1) = p, \text{ since } X_1 \text{ is binomial with } n = 1. \quad E(\hat{p}_2) = E\left(\frac{X}{n}\right) = \frac{1}{n} np = p, \text{ since } X \text{ is}$$

binomial.

$$\text{b) } \text{Var}(\hat{p}_1) = p(1-p); \text{Var}(X) = np(1-p). \text{ Then } \text{Var}(\hat{p}_2) = \frac{np(1-p)}{n^2} = \frac{p(1-p)}{n}, \text{ which}$$

is smaller than  $\text{Var}(\hat{p}_1)$  by a factor of  $n$ .

$$5.4.18 \quad \text{From the solution to Question 5.4.2, } f_{Y_{\max}}(y) = 5 \frac{y^4}{\theta^5}.$$

$$E(Y_{\max}) = \int_0^\theta y \cdot 5 \frac{y^4}{\theta^5} dy = \frac{5}{6} \theta$$

$$E(Y_{\max}^2) = \int_0^\theta y^2 \cdot 5 \frac{y^4}{\theta^5} dy = \frac{5}{7} \theta^2$$

$$\text{Var}(Y_{\max}) = \frac{5}{7} \theta^2 - \left( \frac{5}{6} \theta \right)^2 = \frac{5}{36(7)} \theta^2$$

$$\text{Var}(\hat{\theta}_1) = \text{Var}\left(\frac{6}{5} \cdot Y_{\max}\right) = \frac{36}{25} \frac{5}{36(7)} \theta^2 = \frac{1}{35} \theta^2$$

By symmetry,  $\text{Var}(Y_{\min}) = \text{Var}(Y_{\max})$ .

$$\text{Var}(\hat{\theta}_2) = \text{Var}(6 \cdot Y_{\min}) = 36 \text{Var}(Y_{\min}) = 36 \frac{5}{36(7)} \theta^2 = \frac{5}{7} \theta^2. \text{ Thus, } \frac{6}{5} \cdot Y_{\max} \text{ has smaller}$$

variance. This result makes sense intuitively, since efficiency here depends on the size of the constant needed to make the estimator unbiased.

- 5.4.19** (a) The random variable  $Y_1$  has the same pdf as the random variable in Example 3.5.6, so  $E(Y_1) = \theta$ . Also,  $E(\bar{Y}) = E(Y_1) = \theta$ . Note that  $nY_{\min}$  has the same pdf as  $Y_1$ :

$$f_{Y_{\min}}(y) = nf_Y(y)[1 - F_Y(y)]^{n-1} = n \frac{1}{\theta} e^{-y/\theta} [1 - (1 - e^{-y/\theta})]^{n-1} = n \frac{1}{\theta} e^{-ny/\theta}.$$

$$\text{Then } f_{nY_{\min}}(y) = \frac{1}{n} f_{Y_{\min}}\left(\frac{y}{n}\right) = \frac{1}{n} n \frac{1}{\theta} e^{-n(y/n)/\theta} = \frac{1}{\theta} e^{-y/\theta}$$

- (b)  $\text{Var}(\hat{\theta}_1) = \text{Var}(Y_1) = \theta^2$ , since  $Y_1$  is a gamma variable with parameters 1 and  $1/\theta$ , and  $\text{Var}(\hat{\theta}_3) = \text{Var}(nY_{\min}) = \text{Var}(Y_1) = \theta^2$ .  $\text{Var}(\hat{\theta}_2) = \text{Var}(\bar{Y}) = \text{Var}(Y_1) / n = \theta^2 / n$
- (c)  $\text{Var}(\hat{\theta}_3) / \text{Var}(\hat{\theta}_1) = \theta^2 / \theta^2 = 1$   
 $\text{Var}(\hat{\theta}_3) / \text{Var}(\hat{\theta}_2) = (\theta^2 / n) / \theta^2 = 1 / n$

**5.4.20**  $\text{Var}(\hat{\lambda}_1) = \text{Var}(X_1) = \lambda$ .  $\text{Var}(\hat{\lambda}_2) = \text{Var}(\bar{X}) = \lambda/n$ .  $\text{Var}(\hat{\lambda}_2) / \text{Var}(\hat{\lambda}_1) = (\lambda/n) / \lambda = 1/n$

**5.4.21**  $E(Y_{\max}) = \int_0^\theta y \cdot n \frac{y^{n-1}}{\theta^n} dy = \frac{n}{n+1} \theta$

$$E(Y_{\max}^2) = \int_0^\theta y^2 \cdot n \frac{y^{n-1}}{\theta^n} dy = \frac{n}{n+2} \theta^2$$

$$\text{Var}(Y_{\max}) = \frac{n}{n+2} \theta^2 - \left( \frac{n}{n+1} \theta \right)^2 = \frac{n}{(n+1)^2 (n+2)} \theta^2$$

$$\text{Var}(\hat{\theta}_1) = \text{Var}\left(\frac{n+1}{n} \cdot Y_{\max}\right) = \frac{(n+1)^2}{n^2} \frac{n}{(n+1)^2 (n+2)} \theta^2 = \frac{1}{n(n+2)} \theta^2$$

By symmetry,  $\text{Var}(Y_{\min}) = \text{Var}(Y_{\max})$ .

$$\text{Var}(\hat{\theta}_2) = \text{Var}((n+1)Y_{\min}) = (n+1)^2 \frac{n}{(n+1)^2 (n+2)} \theta^2 = \frac{n}{(n+2)} \theta^2$$

$$\text{Var}(\hat{\theta}_2) / \text{Var}(\hat{\theta}_1) = \frac{n\theta^2}{(n+2)} / \frac{\theta^2}{n(n+2)} = n^2$$

- 5.4.22** We seek the value of  $c$  that minimizes  $\text{Var}[cW_1 + (1-c)W_2]$ .

$$\text{But } \text{Var}[cW_1 + (1-c)W_2] = c^2 \text{Var}(W_1) + (1-c)^2 \text{Var}(W_2) = c^2 \sigma_1^2 + (1-c)^2 \sigma_2^2$$

Differentiate this expression with respect to  $c$  to obtain

$$\frac{\partial [c^2 \sigma_1^2 + (1-c)^2 \sigma_2^2]}{\partial c} = 2c\sigma_1^2 - 2(1-c)\sigma_2^2$$

Setting this derivative equal to zero gives  $c = \frac{\sigma_2^2}{\sigma_1^2 + \sigma_2^2}$

## Section 5.5: Minimum-Variance Estimators: The Cramér-Rao Lower Bound

**5.5.1**  $\ln f_Y(Y; \theta) = -\ln \theta - Y/\theta$

$$\frac{\partial \ln f_Y(Y; \theta)}{\partial \theta} = -\frac{1}{\theta} + Y/\theta^2$$

$$\frac{\partial^2 \ln f_Y(Y; \theta)}{\partial \theta^2} = \frac{1}{\theta^2} - 2Y/\theta^3$$

$$E \left[ \frac{\partial^2 \ln f_Y(Y; \theta)}{\partial \theta^2} \right] = \frac{1}{\theta^2} - 2\theta/\theta^3 = \frac{-1}{\theta^2}, \text{ so the Cramer-Rao bound is } \theta^2/n.$$

Also,  $\text{Var}(\hat{\theta}) = \text{Var}(\bar{Y}) = \text{Var}(Y)/n = \theta^2/n$ , so  $\hat{\theta}$  is a best estimator.

**5.5.2**  $\ln f_X(X; \lambda) = -\lambda + X \ln \lambda - \ln X!$

$$\frac{\partial \ln f_X(X; \lambda)}{\partial \lambda} = -1 + X/\lambda$$

$$\frac{\partial^2 \ln f_X(X; \lambda)}{\partial \lambda^2} = -X/\lambda^2$$

$$E \left[ \frac{\partial^2 \ln f_X(X; \lambda)}{\partial \lambda^2} \right] = -\lambda/\lambda^2 = -1/\lambda, \text{ so the Cramer-Rao bound is } \lambda/n.$$

Also,  $\text{Var}(\hat{\lambda}) = \text{Var}(\bar{X}) = \text{Var}(X)/n = \lambda/n$ , so  $\hat{\lambda}$  is an efficient estimator.

**5.5.3**  $\ln f_Y(Y; \mu) = -\ln \sqrt{2\pi}\sigma - \frac{1}{2} \frac{(Y - \mu)^2}{\sigma^2}$

$$\frac{\partial \ln f_Y(Y; \mu)}{\partial \mu} = \frac{(Y - \mu)}{\sigma^2}$$

$$\frac{\partial^2 \ln f_Y(Y; \mu)}{\partial \mu^2} = \frac{-1}{\sigma^2}$$

$$E \left[ \frac{\partial^2 \ln f_Y(Y; \mu)}{\partial \mu^2} \right] = \frac{-1}{\sigma^2}, \text{ so the Cramer-Rao bound is } \sigma^2/n.$$

Also,  $\text{Var}(\hat{\mu}) = \text{Var}(\bar{Y}) = \text{Var}(Y)/n = \sigma^2/n$ , so  $\hat{\mu}$  is an efficient estimator.

**5.5.4**  $\ln f_Y(Y; \theta) = -\ln \theta$

$$\frac{\partial \ln f_Y(Y; \theta)}{\partial \theta} = \frac{-1}{\theta}$$

$$E \left[ \left( \frac{\partial \ln f_Y(Y; \theta)}{\partial \theta} \right)^2 \right] = \frac{1}{\theta^2}, \text{ so the Cramer-Rao bound is } \frac{\theta^2}{n}.$$

From Question 5.4.21,  $\text{Var}(\hat{\theta}) = \frac{\theta^2}{n(n+2)}$ , which is smaller than the Cramer-Rao bound.

This occurs because Theorem 5.5.1 is not necessarily valid if the interval where the pdf is nonzero depends on the parameter.

**5.5.5**  $\ln f_X(X; \theta) = (X-1)\ln(\theta-1) - X \ln \theta$

$$\frac{\partial \ln f_X(X; \theta)}{\partial \theta} = \frac{X-1}{\theta-1} - \frac{X}{\theta}$$

$$\frac{\partial^2 \ln f_X(X; \theta)}{\partial \theta^2} = -\frac{X-1}{(\theta-1)^2} + \frac{X}{\theta^2}$$

$$E \left( \frac{\partial^2 \ln f_X(X; \theta)}{\partial \theta^2} \right) = -\frac{E(X)-1}{(\theta-1)^2} + \frac{E(X)}{\theta^2} = -\frac{1}{\theta-1} + \frac{1}{\theta} = \frac{-1}{\theta(\theta-1)} \text{ so the Cramer-Rao bound is}$$

$$\frac{\theta(\theta-1)}{n}. \text{ Also, } \text{Var}(\bar{X}) = \frac{\text{Var}(X)}{n} = \frac{\theta(\theta-1)}{n} \text{ so } \bar{X} \text{ is an efficient estimator.}$$

**5.5.6** (a)  $Y$  is a gamma random variable with parameters  $r$  and  $1/\theta$  so  $E(Y) = r\theta$ .

$$\text{Let } \hat{\theta} = \frac{1}{r} \bar{Y} = \frac{1}{rn} \sum_{i=1}^n Y_i. \text{ Then } E(\hat{\theta}) = \frac{1}{rn} \sum_{i=1}^n E(Y_i) = \frac{1}{rn} nr\theta = \theta$$

(b)  $\ln f_Y(Y; \theta) = -\ln(r-1)! - r \ln \theta + (r-1) \ln Y - Y/\theta$

$$\frac{\partial \ln f_Y(Y; \theta)}{\partial \theta} = -r/\theta + Y/\theta^2$$

$$\frac{\partial^2 \ln f_Y(Y; \theta)}{\partial \theta^2} = r/\theta^2 - 2Y/\theta^3$$

$$E\left[\frac{\partial^2 \ln f_Y(Y; \theta)}{\partial \theta^2}\right] = r/\theta^2 - 2(r\theta)/\theta^3 = -r/\theta^2$$

The Cramer-Rao bound is  $\theta^2/rn$ .  $\text{Var}(\hat{\theta}) = \left(\frac{1}{rn}\right)^2 \sum_{i=1}^n \text{Var}(Y_i) = \left(\frac{1}{rn}\right)^2 nr\theta^2 = \theta^2/rn$ , so  $\hat{\theta}$

is a minimum-variance estimator.

5.5.7

$$\begin{aligned} E\left(\frac{\partial^2 \ln f_W(W; \theta)}{\partial \theta^2}\right) &= \int_{-\infty}^{\infty} \frac{\partial}{\partial \theta} \left( \frac{\partial \ln f_W(w; \theta)}{\partial \theta} \right) f_W(w; \theta) dw \\ &= \int_{-\infty}^{\infty} \frac{\partial}{\partial \theta} \left( \frac{1}{f_W(w; \theta)} \frac{\partial f_W(w; \theta)}{\partial \theta} \right) f_W(w; \theta) dw \\ &= \int_{-\infty}^{\infty} \left[ \frac{1}{f_W(w; \theta)} \frac{\partial^2 f_W(w; \theta)}{\partial \theta^2} - \frac{1}{(f_W(w; \theta))^2} \left( \frac{\partial f_W(w; \theta)}{\partial \theta} \right)^2 \right] f_W(w; \theta) dw \\ &= \int_{-\infty}^{\infty} \frac{\partial^2 f_W(w; \theta)}{\partial \theta^2} dw - \int_{-\infty}^{\infty} \frac{1}{(f_W(w; \theta))^2} \left( \frac{\partial f_W(w; \theta)}{\partial \theta} \right)^2 f_W(w; \theta) dw \\ &= 0 - \int_{-\infty}^{\infty} \left( \frac{\partial \ln f_W(w; \theta)}{\partial \theta} \right)^2 f_W(w; \theta) dw \end{aligned}$$

The 0 occurs because  $1 = \int_{-\infty}^{\infty} f_W(w; \theta) dw$ , so  $0 = \frac{\partial^2 \int_{-\infty}^{\infty} f_W(w; \theta) dw}{\partial \theta^2} = \int_{-\infty}^{\infty} \frac{\partial^2 f_W(w; \theta)}{\partial \theta^2} dw$

The above argument shows that  $E\left(\frac{\partial^2 \ln f_W(W; \theta)}{\partial \theta^2}\right) = -E\left(\frac{\partial \ln f_W(W; \theta)}{\partial \theta}\right)^2$ .

Multiplying both sides of the equality by  $n$  and inverting gives the desired equality.

## Section 5.6: Sufficient Estimators

5.6.1

$$\prod_{i=1}^n p_X(k_i; p) = \prod_{i=1}^n (1-p)^{k_i-1} p = (1-p)^{\left(\sum_{i=1}^n k_i\right)-n} p^n$$

Let  $g\left(\sum_{i=1}^n k_i; p\right) = (1-p)^{\left(\sum_{i=1}^n k_i\right)-n} p^n$  and  $u(k_1, \dots, k_n) = 1$ . By Theorem 5.6.1, the statistic

$$\sum_{i=1}^n X_i \text{ is sufficient}$$

$$5.6.2 \quad P((1, 1, 0) | X_1 + 2X_2 + 3X_3 = 3) = \frac{P((1, 1, 0) \text{ and } X_1 + 2X_2 + 3X_3 = 3)}{P(X_1 + 2X_2 + 3X_3 = 3)} =$$

$$\frac{P((1, 1, 0))}{P((1, 1, 0), (0, 0, 1))} = \frac{p^2(1-p)}{p^2(1-p) + p(1-p)^2} = p.$$

Since the conditional probability does depend on the parameter  $p$ , the statistic cannot be sufficient, by Definition 5.6.1.

5.6.3 We must show  $P(W_1 = w_1, W_2 = w_2, \dots, W_n = w_n | g(\hat{\theta}) = \theta_e)$  does not depend on  $\theta$ .

But  $P(W_1 = w_1, W_2 = w_2, \dots, W_n = w_n | g(\hat{\theta}) = \theta_e) = P(W_1 = w_1, W_2 = w_2, \dots, W_n = w_n | \hat{\theta} = g^{-1}(\theta_e))$ , which does not depend on  $\theta$ , because  $\hat{\theta}$  is sufficient.

$$5.6.4 \quad \prod_{i=1}^n \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{1}{2\sigma^2} \sum_{i=1}^n \frac{y_i^2}{\sigma^2}} = \left[ (\sigma^2)^{-n/2} e^{-\frac{1}{2\sigma^2} \left( \sum_{i=1}^n y_i^2 \right)} \right] [2\pi^{-n/2}], \text{ so } \sum_{i=1}^n Y_i^2 \text{ is sufficient by Theorem 5.6.1.}$$

$$5.6.5 \quad \prod_{i=1}^n \frac{1}{(r-1)! \theta^r} y_i^{r-1} e^{-y_i/\theta} = \frac{1}{[(r-1)!]^n} \frac{1}{\theta^n} \left( \prod_{i=1}^n y_i \right)^{r-1} = \left[ \frac{1}{\theta^n} e^{-\frac{1}{\theta} \sum_{i=1}^n y_i} \right] \frac{1}{[(r-1)!]^n} \left( \prod_{i=1}^n y_i \right)^{r-1}$$

so  $\sum_{i=1}^n Y_i$  is a sufficient statistic for  $\theta$ . So also is  $\frac{1}{r} \bar{Y}$ . (See Question 5.6.3)

$$5.6.6 \quad L = \prod_{i=1}^n f_Y(y_i; \theta) = \prod_{i=1}^n \theta y_i^{\theta-1} = \theta^n \left( \prod_{i=1}^n y_i \right)^{\theta-1}, \text{ and } \ln L = n \cdot \ln \theta + (\theta-1) \sum_{i=1}^n \ln y_i$$

$$\frac{d \ln L}{d \theta} = \frac{n}{\theta} + \sum_{i=1}^n \ln y_i$$

$$\text{Setting } \frac{d \ln L}{d \theta} = 0 \text{ gives } \theta_e = \frac{-n}{\sum_{i=1}^n \ln y_i} = \frac{-n}{\ln \left( \prod_{i=1}^n y_i \right)}, \text{ which is a function of } \prod_{i=1}^n y_i.$$

5.6.7 (a) Write the pdf in the form  $f_Y(y) = e^{-(y-\theta)} \cdot I_{[\theta, \infty)}(y)$ , where  $I_{[\theta, \infty)}(y)$  is the indicator function introduced in Example 5.6.2. Then the likelihood function is

$$L(\theta) = \prod_{i=1}^n e^{-(y_i - \theta)} \cdot I_{[\theta, \infty)}(y_i) = e^{-\sum_{i=1}^n y_i} e^{n\theta} \prod_{i=1}^n I_{[\theta, \infty)}(y_i)$$

But  $\prod_{i=1}^n I_{[\theta, \infty)}(y_i) = I_{[\theta, \infty)}(y_{\min})$ , so the likelihood function factors into

$$L(\theta) = \left( e^{-\sum_{i=1}^n y_i} \right) \left[ e^{n\theta} \cdot I_{[\theta, \infty)}(y_{\min}) \right]$$

Thus the likelihood function decomposes in such a way that the factor involving  $\theta$  only contains the  $y_i$ 's through  $y_{\min}$ . By Theorem 5.6.1,  $y_{\min}$  is sufficient.

(b) We need to show that the likelihood function given  $y_{\max}$  is independent of  $\theta$ . But the

$$\text{likelihood function is } \prod_{i=1}^n e^{-(y_i - \theta)} = \begin{cases} e^{\theta} e^{-\sum_{i=1}^n y_i} & \text{if } \theta \leq y_1, y_2, \dots, y_n \\ 0 & \text{otherwise} \end{cases}$$

Regardless of the value of  $y_{\max}$ , the expression for the likelihood does depend on  $\theta$ . If any one of the  $y_i$ , other than  $y_{\max}$ , is less than  $\theta$ , the expression is 0. Otherwise it is non-zero.

**5.6.8** Write the pdf in the form  $f_Y(y) = \frac{1}{\theta} \cdot I_{[0, \theta]}(y)$ . Then the likelihood function is

$$L(\theta) = \prod_{i=1}^n \frac{1}{\theta} \cdot I_{[0, \theta]}(y_i) = \frac{1}{\theta^n} \prod_{i=1}^n I_{[0, \theta]}(y_i)$$

But  $\prod_{i=1}^n I_{[0, \theta]}(y_i) = I_{[0, \theta]}(y_{\max})$ , so the likelihood function factors into

$$L(\theta) = (1) \left[ \frac{1}{\theta^n} \cdot I_{[0, \infty)}(y_{\max}) \right]$$

Thus the likelihood function decomposes in such a way that the factor involving  $\theta$  only contains the  $y_i$ 's through  $y_{\max}$ . By Theorem 5.6.1,  $y_{\max}$  is sufficient.

**5.6.9** 
$$\prod_{i=1}^n g_W(w_i; \theta) = \prod_{i=1}^n e^{K(w_i)p(\theta) + S(w_i) + q(\theta)} = e^{\left( \sum_{i=1}^n K(w_i) \right) p(\theta) + \sum_{i=1}^n S(w_i) + nq(\theta)} = \left( e^{\left( \sum_{i=1}^n K(w_i) \right) p(\theta) + nq(\theta)} \right) \left( e^{\sum_{i=1}^n S(w_i)} \right),$$

so  $\sum_{i=1}^n K(W_i)$  is a sufficient statistic for  $\theta$  by Theorem 5.6.1.

**5.6.10**  $\lambda e^{-\lambda y} = e^{\ln \lambda - \lambda y} = e^{y(-\lambda) + \ln \lambda}$ . Take  $K(y) = y$ ,  $p(\lambda) = -\lambda$ ,  $S(y) = 0$ , and  $q(\lambda) = \ln \lambda$ .

Then  $\sum_{i=1}^n Y_i$  is sufficient.

**5.6.11**  $\theta(1+y)^{\theta+1} = e^{\ln \theta - (\theta+1) \ln(1+y)} = e^{[\ln(1+y)](-\theta-1) + \ln \theta}$ . Take  $K(y) = \ln(1+y)$ ,  $p(\theta) = -\theta - 1$ ,

and  $q(\theta) = \ln \theta$ . Then  $\sum_{i=1}^n K(Y_i) = \sum_{i=1}^n \ln(1+Y_i)$  is sufficient for  $\theta$ .

## Section 5.7: Consistency

**5.7.1**  $P(16 < \bar{Y} < 20) = 0.90$  is equivalent to  $P\left(\frac{16-18}{5.0/\sqrt{n}} < Z < \frac{20-18}{5.0/\sqrt{n}}\right) = 0.90$ , or

$P(-0.40\sqrt{n} < Z < 0.40\sqrt{n}) = 0.90$ . Then  $0.40\sqrt{n} = 1.64$  or  $n = \left(\frac{1.64}{0.40}\right)^2 = 16.81$ , so take  $n = 17$ .

**5.7.2** Since  $\mu = 0$ , for each  $i$ ,  $E(Y_i^2) = \sigma^2$ . By the weak law of large numbers demonstrated in

Example 5.7.2,  $\frac{1}{n} \sum_{i=1}^n Y_i^2$  is a consistent estimator of the mean of the  $Y_i^2$ , in this case  $\sigma^2$ .

However, the proof given in the example requires that  $\text{Var}(Y_i^2) < \infty$ . This follows from an application of the moment generating function for the normal distribution.

**5.7.3** (a)  $P(Y_1 > 2\lambda) = \int_{2\lambda}^{\infty} \lambda e^{-\lambda y} dy = e^{-2\lambda^2}$ . Then  $P(|Y_1 - \lambda| < \lambda/2) < 1 - e^{-2\lambda^2} < 1$ .

Thus,  $\lim_{n \rightarrow \infty} P(|Y_1 - \lambda| < \lambda/2) < 1$ .

(b)  $P\left(\sum_{i=1}^n Y_i > 2\lambda\right) \geq P(Y_1 > 2\lambda) = e^{-2\lambda^2}$ . The proof now proceeds along the lines of Part (a).

$$\begin{aligned}
5.7.4 \quad (a) \quad & \text{Let } \mu_n = E(\hat{\theta}_n). \quad E[(\hat{\theta}_n - \theta)^2] = E[(\hat{\theta}_n - \mu_n + \mu_n - \theta)^2] \\
&= E[(\hat{\theta}_n - \mu_n)^2 + (\mu_n - \theta)^2 + 2(\hat{\theta}_n - \mu_n)(\mu_n - \theta)] \\
&= E[(\hat{\theta}_n - \mu_n)^2] + E[(\mu_n - \theta)^2] + 2(\mu_n - \theta)E[(\hat{\theta}_n - \mu_n)] \\
&= E[(\hat{\theta}_n - \mu_n)^2] + (\mu_n - \theta)^2 + 0 \quad \text{or} \quad E[(\hat{\theta}_n - \theta)^2] = E[(\hat{\theta}_n - \mu_n)^2] + (\mu_n - \theta)^2
\end{aligned}$$

The left hand side of the equation tends to 0 by the squared-error consistency hypothesis.

Since the two summands on the right hand side are non-negative, each of them must tend to

zero also. Thus,  $\lim_{n \rightarrow \infty} (\mu_n - \theta)^2 = 0$ , which implies  $\lim_{n \rightarrow \infty} (\mu_n - \theta) = 0$ , or  $\lim_{n \rightarrow \infty} \mu_n = \theta$ .

(b) By Part (a)  $\lim_{n \rightarrow \infty} \mu_n - \theta = 0$ .

$$\begin{aligned}
& \text{For any } \varepsilon > 0, \quad \lim_{n \rightarrow \infty} P(|\hat{\theta}_n - \theta| \geq \varepsilon) = \lim_{n \rightarrow \infty} P(|(\hat{\theta}_n - \mu_n) - (\mu_n - \theta)| \geq \varepsilon) \\
&= \lim_{n \rightarrow \infty} P(|\hat{\theta}_n - \mu_n| \geq \varepsilon) \leq \frac{\text{Var}(\hat{\theta}_n)}{\varepsilon^2} \quad \text{by Chebyshev's Inequality.}
\end{aligned}$$

$$\text{But } \frac{\text{Var}(\hat{\theta}_n)}{\varepsilon^2} = \frac{E[(\hat{\theta}_n - \mu_n)^2]}{\varepsilon^2}, \text{ and by Part (a), } \lim_{n \rightarrow \infty} E[(\hat{\theta}_n - \mu_n)^2] = 0,$$

so  $\lim_{n \rightarrow \infty} P(|\hat{\theta}_n - \theta| \geq \varepsilon) = 0$ . Thus,  $\hat{\theta}_n$  is consistent.

$$\begin{aligned}
5.7.5 \quad & E[(Y_{\max} - \theta)^2] = \int_0^\theta (y - \theta)^2 \frac{n}{\theta} \left(\frac{y}{\theta}\right)^{n-1} dy \\
&= \frac{n}{\theta^n} \int_0^\theta (y^{n+1} - 2\theta y^n + \theta^2 y^{n-1}) dy = \frac{n}{\theta^n} \left( \frac{\theta^{n+2}}{n+2} - \frac{2\theta^{n+2}}{n+1} + \frac{\theta^{n+2}}{n} \right) = \left( \frac{n}{n+2} - \frac{2n}{n+1} + 1 \right) \theta^2 \\
&\text{Then } \lim_{n \rightarrow \infty} E[(Y_{\max} - \theta)^2] = \lim_{n \rightarrow \infty} \left( \frac{n}{n+2} - \frac{2n}{n+1} + 1 \right) \theta^2 = 0 \text{ and the estimator is squared error} \\
&\text{consistent.}
\end{aligned}$$

**5.7.6** Because the symmetry of the pdf, the mean of the sample median is  $\mu$ . Chebyshev's

inequality applies and  $P(|Y'_{n+1} - \mu| < \varepsilon) > 1 - \frac{\text{Var}(Y'_{n+1})}{\varepsilon^2}$ .

Now,  $\lim_{n \rightarrow \infty} \text{Var}(Y'_{n+1}) = \lim_{n \rightarrow \infty} \frac{1}{8[f_Y(\mu; \mu)]^2 n} = 0$ , so  $\lim_{n \rightarrow \infty} P(|Y'_{n+1} - \mu| < \varepsilon) = 1$ , and  $Y_{n+1}$  is consistent for  $\mu$ .

## Section 5.8: Bayesian Estimation

**5.8.1** The numerator of  $g_{\Theta}(\theta | X = k)$  is  $p_X(k | \theta)f_{\Theta}(\theta) =$

$$[(1 - \theta)^{k-1} \theta] \frac{\Gamma(r+s)}{\Gamma(r)\Gamma(s)} \theta^{r-1} (1 - \theta)^{s-1} = \frac{\Gamma(r+s)}{\Gamma(r)\Gamma(s)} \theta^r (1 - \theta)^{s+k-2}$$

The term  $\theta^r (1 - \theta)^{s+k-2}$  is the variable part of the beta distribution with parameters  $r + 1$  and  $s + k - 1$ , so that is the pdf of  $g_{\Theta}(\theta | X = k)$ .

**5.8.2** The Bayes estimate is the mean of the posterior distribution, a beta pdf with a parameters  $k + 4$

and  $n - k + 102$ . The mean of this pdf is  $\frac{k + 4}{k + 4 + n - k + 102} = \frac{k + 4}{n + 106}$ .

Note we can write  $\frac{k + 4}{n + 106} = \frac{n}{n + 106} \left( \frac{k}{n} \right) + \frac{106}{n + 106} \left( \frac{4}{106} \right)$

**5.8.3** (a) Following the pattern of Example 5.8.2, we can see that the posterior distribution is a beta pdf with parameters  $k + 135$  and  $n - k + 135$ .

(b) The mean of the Bayes pdf given in part (a) is  $\frac{k + 135}{k + 135 + n - k + 135} = \frac{k + 135}{n + 270}$ ,

Note we can write  $\frac{k + 135}{n + 270} = \frac{n}{n + 270} \left( \frac{k}{n} \right) + \frac{270}{n + 270} \left( \frac{135}{270} \right) = \frac{n}{n + 270} \left( \frac{k}{n} \right) + \frac{270}{n + 270} \left( \frac{1}{2} \right)$

**5.8.4**  $\frac{k + 1}{n + 2} = \frac{n}{n + 2} \left( \frac{k}{n} \right) + \frac{2}{n + 2} \left( \frac{1}{2} \right)$

**5.8.5** In each case the estimator is biased, since the mean of the estimator is a weighted average of the unbiased maximum likelihood estimator and a non-zero constant. However, in each case, the weighting on the maximum likelihood estimator tends to 1 as  $n$  tends to  $\infty$ , so these estimators are asymptotically unbiased.

**5.8.6** The numerator of  $g_{\Theta}(\theta | X = k)$  is  $f_Y(y | \theta)f_{\Theta}(\theta) =$

$$\frac{\theta^r}{\Gamma(r)} y^{r-1} e^{-\theta y} \frac{\mu^s}{\Gamma(s)} \theta^{s-1} e^{-\mu \theta} = \frac{\mu^s y^{r-1}}{\Gamma(r)\Gamma(s)} \theta^{r+s-1} e^{-(y+\mu)\theta}$$

We recognize the part involving  $\theta$  as the variable part of the gamma distribution with parameters  $r + s$  and  $y + \mu$ , so that is  $g_{\Theta}(\theta | X = k)$ .

**5.8.7** Since the sum of gamma random variables is gamma, then  $W$  is gamma with parameters  $nr$  and  $\lambda$ . Then  $g_{\Theta}(\theta | X = k)$  is a gamma pdf with parameters  $nr + s$  and  $\sum_{i=1}^n y_i + \mu$ .

**5.8.8** The Bayes estimate is the mean of the posterior pdf, which in this case is  $\frac{nr + s}{\sum_{i=1}^n y_i + \mu}$

**5.8.9** 
$$p_X(k | \theta) f_{\Theta}(\theta) = \binom{n}{k} \frac{\Gamma(r+s)}{\Gamma(r)\Gamma(s)} \theta^{k+r-1} (1-\theta)^{n-k+s-1},$$

$$\text{so } p_X(k | \theta) = \binom{n}{k} \frac{\Gamma(r+s)}{\Gamma(r)\Gamma(s)} \int_0^1 \theta^{k+r-1} (1-\theta)^{n-k+s-1} d\theta,$$

$$= \binom{n}{k} \frac{\Gamma(r+s)}{\Gamma(r)\Gamma(s)} \frac{\Gamma(k+r)\Gamma(n-k+s)}{\Gamma(n+r+s)} = \frac{n!}{k!(n-k)!} \frac{(r+s-1)!}{(r-1)!(s-1)!} \frac{(k+r-1)!(n-k+s-1)!}{(n+r+s-1)!}$$

$$= \frac{(k+r-1)!(n-k+s-1)!}{k!(r-1)!(n-k)!(s-1)!} \frac{n!(r+s-1)!}{(n+r+s-1)!}$$

$$= \binom{k+r-1}{k} \binom{n-k+s-1}{n-k} \bigg/ \binom{n+r+s-1}{n}$$

# Chapter 6: Hypothesis Testing

## Section 6.2: The Decision Rule

- 6.2.1** (a) Reject  $H_0$  if  $\frac{\bar{y} - 120}{18 / \sqrt{25}} \leq -1.41$ ;  $z = -1.61$ ; reject  $H_0$ .  
 (b) Reject  $H_0$  if  $\frac{\bar{y} - 42.9}{3.2 / \sqrt{16}}$  is either  $\leq -2.58$  or  $\geq 2.58$ ;  $z = 2.75$ ; reject  $H_0$ .  
 (c) Reject  $H_0$  if  $\frac{\bar{y} - 14.2}{4.1 / \sqrt{9}} \geq 1.13$ ;  $z = 1.17$ ; reject  $H_0$ .
- 6.2.2** Let  $\mu$  = true average IQ of students after drinking Brain-Blaster. To test  $H_0: \mu = 95$  versus  $H_1: \mu \neq 95$  at the  $\alpha = 0.06$  level of significance, the null hypothesis should be rejected if  $z = \frac{\bar{y} - 95}{15 / \sqrt{22}}$  is either  $\leq -1.88$  or  $\geq 1.88$ . Equivalently,  $H_0$  will be rejected if  $\bar{y}$  is either  

$$1) \leq 95 - (1.88) \frac{15}{\sqrt{22}} = 89.0 \text{ or } 2) \geq 95 + (1.88) \frac{15}{\sqrt{22}} = 101.0.$$
- 6.2.3** (a) No, because the observed  $z$  could fall between the 0.05 and 0.01 cutoffs.  
 (b) Yes. If the observed  $z$  exceeded the 0.01 cutoff, it would necessarily exceed the 0.05 cutoff.
- 6.2.4** Assuming there is no reason to suspect that the polymer would shorten a tire's lifetime, the alternative hypothesis should be  $H_1: \mu > 32,500$ . At the  $\alpha = 0.05$  level,  $H_0$  should be rejected if the test statistic exceeds  $z_{.05} = 1.64$ . But  $z = \frac{33,800 - 32,500}{4000 / \sqrt{15}} = 1.26$ , implying that the observed mileage increase is not statistically significant.
- 6.2.5** No, because two-sided cutoffs (for a given  $\alpha$ ) are further away from 0 than one-sided cutoffs.
- 6.2.6** By definition,  $\alpha = P(29.9 \leq \bar{Y} \leq 30.1 | H_0 \text{ is true}) = P\left(\frac{29.9 - 30}{6.0 / \sqrt{16}} \leq \frac{\bar{Y} - 30}{6.0 / \sqrt{16}} \leq \frac{30.1 - 30}{6.0 / \sqrt{16}}\right) = P(-0.07 \leq Z \leq 0.07) = 0.056$ . The interval (29.9, 30.1) is a poor choice for  $C$  because it rejects  $H_0$  for the  $\bar{y}$ -values that are most compatible with  $H_0$  (that is, closest to  $\mu_0 = 30$ ). Since the alternative is two-sided,  $H_0$  should be rejected if  $\bar{y}$  is either  

$$1) \leq 30 - 1.91 \cdot \frac{6.0}{\sqrt{16}} = 27.1 \text{ or } 2) \geq 30 + 1.91 \cdot \frac{6.0}{\sqrt{16}} = 32.9.$$
- 6.2.7** (a)  $H_0$  should be rejected if  $\frac{\bar{y} - 12.6}{0.4 / \sqrt{30}}$  is either  $\leq -1.96$  or  $\geq 1.96$ . But  $\bar{y} = 12.76$  and  $z = 2.19$ , suggesting that the machine should be readjusted.  
 (b) The test assumes that the  $y_i$ 's constitute a random sample from a normal distribution. Graphed, a histogram of the 30  $y_i$ 's shows a mostly bell-shaped pattern. There is no reason to suspect that the normality assumption is not being met.

- 6.2.8** (a) Obs.  $z = -1.61$ , so  $P\text{-value} = P(Z \leq -1.61) = 0.0537$ .  
 (b) Obs.  $z = 2.75$ , so  $P\text{-value} = P(Z \leq -2.75) + P(Z \geq 2.75) = 0.0030 + 0.0030 = 0.0060$ .  
 (c) Obs.  $z = 1.17$ , so  $P\text{-value} = P(Z \geq 1.17) = 0.1210$ .  
 Yes, all the  $P$ -values agree with the decisions reached in Question 6.2.1.
- 6.2.9**  $P\text{-value} = P(Z \leq -0.92) + P(Z \geq 0.92) = 0.3576$ ;  $H_0$  would be rejected if  $\alpha$  had been set at any value greater than or equal to 0.3576.
- 6.2.10** Let  $\mu$  = true average blood pressure when taking statistics exams. Test  $H_0: \mu = 120$  versus  $H_1: \mu > 120$ . Given that  $\sigma = 12$ ,  $n = 50$  and  $\bar{y} = 125.2$ ,  $z = \frac{125.2 - 120}{12 / \sqrt{50}} = 3.06$ . The corresponding  $P$ -value is approximately 0.001 ( $= P(Z \geq 3.06)$ ), so  $H_0$  would be rejected for any usual choice of  $\alpha$ .
- 6.2.11**  $H_0$  should be rejected if  $\frac{\bar{y} - 145.75}{9.50 / \sqrt{25}}$  is either  $\leq -1.96$  or  $\geq 1.96$ . Here,  $\bar{y} = 149.75$  and  $z = 2.10$ , so the difference between \$145.75 and \$149.75 is statistically significant.

## Section 6.3: Testing Binomial Data

- 6.3.1** (a) Given that the technique worked  $k = 24$  times during the  $n = 52$  occasions it was tried,  
 $z = \frac{24 - 52(0.40)}{\sqrt{52(0.40)(0.60)}} = 0.91$ . The latter is not larger than  $z_{.05} = 1.64$ , so  $H_0: p = 0.40$  would not be rejected at the  $\alpha = 0.05$  level. These data do not provide convincing evidence that transmitting predator sounds helps to reduce the number of whales in fishing waters.  
 (b)  $P\text{-value} = P(Z \geq 0.91) = 0.1814$ ;  $H_0$  would be rejected for any  $\alpha \geq 0.1814$ .
- 6.3.2** Let  $p = P(A/\text{HeJ mouse is right-pawed})$ . Test  $H_0: p = 0.67$  versus  $H_1: p \neq 0.67$ . For  $\alpha = 0.05$ ,  $H_0$  should be rejected if  $z$  is either  $\leq -1.96$  or  $\geq 1.96$ . Here,  $n = 35$  and  $k =$  number of right-pawed HeJ mice  $= 18$ , so  $z = \frac{18 - 35(0.67)}{\sqrt{35(0.67)(0.33)}} = -1.96$ , implying that  $H_0$  should be rejected.
- 6.3.3** Let  $p = P(\text{current supporter is male})$ . Test  $H_0: p = 0.65$  versus  $H_1: p < 0.65$ . Since  $n = 120$  and  $k =$  number of male supporters  $= 72$ ,  $z = \frac{72 - 120(0.65)}{\sqrt{120(0.65)(0.35)}} = -1.15$ , which is not less than or equal to  $-z_{.05} (= -1.64)$ , so  $H_0: p = 0.65$  would not be rejected.
- 6.3.4** The null hypothesis would be rejected if  $z = \frac{k - 200(0.45)}{\sqrt{200(0.45)(0.55)}} \geq 1.08 (= z_{.14})$ . For that to happen,  $k \geq 200(0.45) + 1.08 \cdot \sqrt{200(0.45)(0.55)} \doteq 98$ .

- 6.3.5** Let  $p = P(Y_i \leq 0.69315)$ . Test  $H_0: p = \frac{1}{2}$  versus  $H_1: p \neq \frac{1}{2}$ . Given that  $k = 26$  and  $n = 60$ ,  $P\text{-value} = P(X \leq 26) + P(X \geq 34) = 0.3030$ .
- 6.3.6** Let  $p = P(\text{person dies if month preceding birthmonth})$ . Test  $H_0: p = \frac{1}{12}$  versus  $H_1: p < \frac{1}{12}$ . Given that  $\alpha = 0.05$ ,  $H_0$  should be rejected if  $z \leq -1.64$ . In this case,  $z = \frac{16 - 348(1/12)}{\sqrt{348(1/12)(11/12)}} = -2.52$ , which suggests that people do not necessarily die randomly with respect to the month in which they were born. More specifically, there appears to be a tendency to “postpone” dying until the next birthday has passed.
- 6.3.7** Reject  $H_0$  if  $k \geq 4$  gives  $\alpha = 0.50$ ; reject  $H_0$  if  $k \geq 5$  gives  $\alpha = 0.23$ ; reject  $H_0$  if  $k \geq 6$  gives  $\alpha = 0.06$ ; reject  $H_0$  if  $k \geq 7$  gives  $\alpha = 0.01$ .
- 6.3.8** Let  $A_1$  be the event that “ $k \geq 8$ ” is the rejection region being used, and let  $A_2$  be the event that “ $k = 9$ ” is the rejection region being used. Define  $B$  to be the event that  $H_0: p = 0.6$  is rejected. From Theorem 2.4.1,  $P(B) = P(B|A_1)P(A_1) + P(B|A_2)P(A_2)$ . But  $P(B|A_1) = 0.060466 + 0.010078 = 0.070544$  and  $P(B|A_2) = 0.010078$ . If  $p$  denotes the probability that  $A_1$  occurs,  $0.05 = \text{desired } \alpha = 0.070544 \cdot p + 0.010078 \cdot (1 - p)$ , which implies that  $p = 0.66$ . It follows that the probability of rejecting  $H_0$  will be 0.05 if the “ $k \geq 8$ ” decision rule is used 66% of the time and the “ $k = 9$ ” decision rule is used the remaining 34% of the time.
- 6.3.9** (a)  $\alpha = P(\text{reject } H_0 | H_0 \text{ is true}) = P(X \leq 3 | p = 0.75) = \sum_{k=0}^3 \binom{7}{k} (0.75)^k (0.25)^{7-k} = 0.07$
- (b)
- | $p$  | $P(X \leq 3   p)$ |
|------|-------------------|
| 0.75 | 0.07              |
| 0.65 | 0.20              |
| 0.55 | 0.39              |
| 0.45 | 0.61              |
| 0.35 | 0.80              |
| 0.25 | 0.93              |
| 0.15 | 0.99              |

## Section 6.4: Type I and Type II Errors

- 6.4.1** (a) As described in Example 6.2.1,  $H_0: \mu = 494$  is to be tested against  $H_1: \mu \neq 494$  using  $\pm 1.96$  as the  $\alpha = 0.05$  cutoffs. That is,  $H_0$  is rejected if  $\frac{\bar{y} - 494}{124 / \sqrt{86}} \leq -1.96$  or if  $\frac{\bar{y} - 494}{124 / \sqrt{86}} \geq 1.96$ . Equivalently, the null hypothesis is rejected if  $\bar{y} \leq 467.8$  or if  $\bar{y} \geq 520.2$ . Therefore,  $1 - \beta = P(\text{reject } H_0 | \mu = 500) = P(\bar{Y} \leq 467.8 | \mu = 500) + P(\bar{Y} \geq 520.2 | \mu = 500)$

$$\begin{aligned}
&= P\left(Z \leq \frac{467.8 - 500}{124 / \sqrt{86}}\right) + P\left(Z \geq \frac{520.2 - 500}{124 / \sqrt{86}}\right) = P(Z \leq -2.41) + P(Z \geq 1.51) \\
&= 0.0080 + 0.0655 = 0.0735.
\end{aligned}$$

**6.4.2** When  $\alpha = 0.10$ ,  $H_0$  is rejected if  $\frac{\bar{y} - 25.0}{2.4 / \sqrt{30}} \geq 1.28 (= z_{.10})$ . Solving for  $\bar{y}$  shows that the decision rule can be re-expressed as “Reject  $H_0$  if  $\bar{y} \geq 25.0 + 1.28 \cdot \frac{2.4}{\sqrt{30}} = 25.561$ .”

**6.4.3** The null hypothesis in Question 6.2.2 is rejected if  $\bar{y}$  is either  $\leq 89.0$  or  $\geq 101.0$ . Suppose  $\mu = 90$ . Since  $\sigma = 15$  and  $n = 22$ ,  $1 - \beta = P(\bar{Y} \leq 89.0) + P(\bar{Y} \geq 101.0)$

$$\begin{aligned}
&= P\left(Z \leq \frac{89.0 - 90}{15 / \sqrt{22}}\right) + P\left(Z \geq \frac{101.0 - 90}{15 / \sqrt{22}}\right) = P(Z \leq -0.31) + P(Z \geq 3.44) = 0.3783 + 0.0000 \\
&= 0.3783.
\end{aligned}$$

**6.4.4** For  $n = 16$ ,  $\sigma = 4$ , and  $\alpha = 0.05$ ,  $H_0: \mu = 60$  should be rejected in favor of a two-sided  $H_1$  if either  $\bar{y} \leq 60 - 1.96 \cdot \frac{4}{\sqrt{16}} = 58.04$  or  $\bar{y} \geq 60 + 1.96 \cdot \frac{4}{\sqrt{16}} = 61.96$ . Then, for arbitrary  $\mu$ ,  $1 - \beta = P(\bar{Y} \leq 58.04 | \mu) + P(\bar{Y} \geq 61.96 | \mu)$ . Selected values of  $(\mu, 1 - \beta)$  that would lie on the power curve are listed in the accompanying table.

$\mu$	$1 - \beta$
56	0.9793
57	0.8508
58	0.5160
59	0.1700
60	0.05 ( $=\alpha$ )
61	0.1700
62	0.5160
63	0.8508
64	0.9793

**6.4.5**  $H_0$  should be rejected if  $z = \frac{\bar{y} - 240}{50 / \sqrt{25}} \leq -2.33$  or, equivalently, if  $\bar{y} \leq 240 - 2.33 \cdot \frac{50}{\sqrt{25}} = 216.7$ . Suppose  $\mu = 220$ . Then  $\beta = P(\text{accept } H_0 | H_1 \text{ is true}) = P(\bar{Y} > 216.7 | \mu = 220)$

$$= P\left(Z > \frac{216.7 - 220}{50 / \sqrt{25}}\right) = P(Z > -0.33) = 0.6293.$$

**6.4.6** (a) In order for  $\alpha$  to be 0.07,  $P(60 - \bar{y}^* \leq \bar{Y} \leq 60 + \bar{y}^* | \mu = 60) = 0.07$ . Equivalently,

$$P\left(\frac{60 - \bar{y}^* - 60}{8.0 / \sqrt{36}} \leq \frac{\bar{Y} - 60}{8.0 / \sqrt{36}} \leq \frac{60 + \bar{y}^* - 60}{8.0 / \sqrt{36}}\right) = P(-0.75\bar{y}^* \leq Z \leq 0.75\bar{y}^*) = 0.07. \text{ But }$$

$P(-0.09 \leq Z \leq 0.09) = 0.07$ , so  $0.75\bar{y}^* = 0.09$ , which implies that  $\bar{y}^* = 0.12$ .

$$(b) 1 - \beta = P(\text{reject } H_0 | H_1 \text{ is true}) = P(59.88 \leq \bar{Y} \leq 60.12 | \mu = 62) \\ = P\left(\frac{59.88 - 62}{8.0 / \sqrt{36}} \leq Z \leq \frac{60.12 - 62}{8.0 / \sqrt{36}}\right) = P(-1.59 \leq Z \leq -1.41) = 0.0793 - 0.0559 = 0.0234.$$

(c) For  $\alpha = 0.07$ ,  $\pm z_{\alpha/2} = \pm 1.81$  and  $H_0$  should be rejected if  $\bar{y}$  is either

$$1) \leq 60 - 1.81 \cdot \frac{8.0}{\sqrt{36}} = 57.50 \text{ or } 2) \geq 60 + 1.81 \cdot \frac{8.0}{\sqrt{36}} = 62.41. \text{ Suppose } \mu = 62. \text{ Then} \\ 1 - \beta = P(\bar{Y} \leq 57.59 | \mu = 62) + P(\bar{Y} \geq 62.41 | \mu = 62) = P(Z \leq -3.31) + P(Z \geq 0.31) \\ = 0.0005 + 0.3783 = 0.3788.$$

**6.4.7** For  $\alpha = 0.10$ ,  $H_0: \mu = 200$  should be rejected if  $\bar{y} \leq 200 - 1.28 \cdot \frac{15.0}{\sqrt{n}}$ . Also,  $1 - \beta =$   
 $P\left(\bar{Y} \leq 200 - 1.28 \cdot \frac{15.0}{\sqrt{n}} \mid \mu = 197\right) = 0.75$ , so  $P\left(\frac{200 - 1.28 \cdot 15.0 / \sqrt{n} - 197}{15.0 / \sqrt{n}}\right) = 0.75$ . But  
 $P(Z \leq 0.67) = 0.75$ , implying that  $\frac{200 - 1.28 \cdot 15.0 / \sqrt{n} - 197}{15.0 / \sqrt{n}} = 0.67$ . It follows that the  
smallest  $n$  satisfying the conditions placed on  $\alpha$  and  $1 - \beta$  is 95.

**6.4.8** If  $n = 45$ ,  $H_0$  will be rejected when  $\bar{y}$  is either (1)  $\leq 10 - 1.96 \cdot \frac{4}{\sqrt{45}} = 8.83$  or  
(2)  $\geq 10 + 1.96 \cdot \frac{4}{\sqrt{45}} = 11.17$ . When  $\mu = 12$ ,  $\beta = P(\text{accept } H_0 | H_1 \text{ is true}) =$   
 $P(8.83 \leq \bar{Y} \leq 11.17 | \mu = 12) = P\left(\frac{8.83 - 12}{4 / \sqrt{45}} \leq Z \leq \frac{11.17 - 12}{4 / \sqrt{45}}\right) = P(-5.32 \leq Z \leq -1.39) =$   
0.0823. It follows that a sample of size  $n = 45$  is sufficient to keep  $\beta$  smaller than 0.20 when  
 $\mu = 12$ .

**6.4.9** Since  $H_1$  is one-sided,  $H_0$  is rejected when  $\bar{y} \geq 30 + z_\alpha \cdot \frac{9}{\sqrt{16}}$ . Also,  $1 - \beta = \text{power} =$   
 $P\left(\bar{Y} \geq 30 + z_\alpha \cdot \frac{9}{\sqrt{16}} \mid \mu = 34\right) = 0.85$ . Therefore,  $1 - \beta = P\left(Z \geq \frac{30 + z_\alpha \cdot 9 / \sqrt{16} - 34}{9 / \sqrt{16}}\right) =$   
0.85. But  $P(Z \geq -1.04) = 0.85$ , so  $\frac{30 + z_\alpha \cdot 9 / \sqrt{16} - 34}{9 / \sqrt{16}} = -1.04$ , implying that  $z_\alpha = 0.74$ .  
Therefore,  $\alpha = 0.23$ .

**6.4.10** (a)  $P(\text{Type I error}) = P(\text{reject } H_0 | H_0 \text{ is true}) = P(Y \geq 3.20 | \lambda = 1) = \int_{3.20}^{\infty} e^{-y} dy = 0.04$ .

(b)  $P(\text{Type II error}) =$

$$P(\text{accept } H_0 | H_1 \text{ is true}) = P\left(Y < 3.20 \mid \lambda = \frac{4}{3}\right) = \int_0^{3.20} \frac{3}{4} e^{-3y/4} dy = \int_0^{2.4} e^{-u} du = 0.91.$$

**6.4.11** In this context,  $\alpha$  is the proportion of incorrect decisions made on innocent suspects—that is,  $\frac{9}{140}$ , or 0.064. Similarly,  $\beta$  is the proportion of incorrect decisions made on guilty

suspects—here,  $\frac{15}{140}$ , or 0.107. A Type I error (convicting an innocent defendant) would be considered more serious than a Type II error (acquitting a guilty defendant).

**6.4.12** Let  $X$  = number of white chips in sample. Then  $\alpha = P(X \geq 2 | \text{urn has 5 white and 5 red}) = \frac{\binom{5}{2}\binom{5}{1}}{\binom{10}{3}} + \frac{\binom{5}{3}\binom{5}{0}}{\binom{10}{3}} = \frac{1}{2}$ . When the urn is 60% white,  $\beta = P(X \leq 1 | \text{urn has 6$

white and 4 red) =  $\frac{\binom{6}{0}\binom{4}{3}}{\binom{10}{3}} + \frac{\binom{6}{1}\binom{4}{2}}{\binom{10}{3}} = \frac{1}{3}$ . When the urn is 70% white,

$$\beta = P(X \leq 1 | \text{urn has 7 white and 3 red}) = \frac{\binom{7}{0}\binom{3}{3}}{\binom{10}{3}} + \frac{\binom{7}{1}\binom{3}{2}}{\binom{10}{3}} = \frac{11}{60}.$$

**6.4.13** For a uniform pdf,  $f_{Y_{\max}}(y) = \frac{5}{\theta} \left(\frac{y}{\theta}\right)^4$ ,  $0 \leq y \leq \theta$  when  $n = 5$ .

Therefore,  $\alpha = P(\text{reject } H_0 | H_0 \text{ is true}) = P(Y_{\max} \geq k | \theta = 2) = \int_k^2 \frac{5}{2} \left(\frac{y}{2}\right)^4 dy = 1 - \frac{k^5}{32}$ . For  $\alpha$  to be 0.05,  $k = 1.98$ .

**6.4.14** Level of significance =  $\alpha = P(\text{reject } H_0 | H_0 \text{ is true}) = P(Y \geq 0.90 | f_Y(y) = 2y, 0 \leq y \leq 1) = \int_{0.90}^1 2y dy = 0.19$ .

**6.4.15**  $\beta = P(\text{accept } H_0 | H_1 \text{ is true}) = P(X \leq n-1 | p) = 1 - P(X = n | p) = 1 - \binom{n}{n} p^n (1-p)^0 = 1 - p^n$ .  
When  $\beta = 0.05$ ,  $p = \sqrt[n]{0.95}$ .

**6.4.16** If  $H_0$  is true,  $X = X_1 + X_2$  has a binomial distribution with  $n = 6$  and  $p = \frac{1}{2}$ .

$$\text{Therefore, } \alpha = P(\text{reject } H_0 | H_0 \text{ is true}) = P\left(X \geq 5 \mid p = \frac{1}{2}\right) = \sum_{k=5}^6 \binom{6}{k} \left(\frac{1}{2}\right)^k \left(1 - \frac{1}{2}\right)^{6-k} = 7/2^6 = 0.11.$$

**6.4.17**  $1 - \beta = P(\text{reject } H_0 | H_1 \text{ is true}) = P\left(Y \leq \frac{1}{2} \mid \theta\right) = \int_0^{1/2} (1 + \theta)y^\theta dy = y^{\theta+1} \Big|_0^{1/2} = \left(\frac{1}{2}\right)^{\theta+1}$

**6.4.18** (a)  $\alpha = P(\text{reject } H_0 | H_0 \text{ is true}) = P(X \leq 2 | \lambda = 6) = \sum_{k=0}^2 \frac{e^{-6} 6^k}{k!} = 0.062$ .

$$\begin{aligned} \text{(b) } \beta &= P(\text{accept } H_0 | H_1 \text{ is true}) = P(X \geq 3 | \lambda = 4) = 1 - P(X \leq 2 | \lambda = 4) = 1 - \sum_{k=0}^2 \frac{e^{-4} 4^k}{k!} \\ &= 1 - 0.238 = 0.762 \end{aligned}$$

$$\text{6.4.19} \quad P(\text{Type II error}) = \beta = P(\text{accept } H_0 | H_1 \text{ is true}) = P\left(X \leq 3 \mid p = \frac{1}{2}\right) = \sum_{k=1}^3 \left(1 - \frac{1}{2}\right)^{k-1} \cdot \frac{1}{2} = \frac{7}{8}$$

$$\text{6.4.20} \quad \beta = P(\text{accept } H_0 | H_1 \text{ is true}) = P(Y < \ln 10 | \lambda) = \int_0^{\ln 10} \lambda e^{-\lambda y} dy = 1 - e^{-\lambda \ln 10} = 1 - 10^{-\lambda}$$

**6.4.21**  $\alpha = P(\text{reject } H_0 | H_0 \text{ is true}) = P(Y_1 + Y_2 \leq k | \theta = 2)$ . When  $H_0$  is true,  $Y_1$  and  $Y_2$  are uniformly distributed over the square defined by  $0 \leq Y_1 \leq 2$  and  $0 \leq Y_2 \leq 2$ , so the joint pdf of  $Y_1$  and  $Y_2$  is a plane parallel to the  $Y_1 Y_2$ -axis at height  $\frac{1}{4} \left( = f_{Y_1}(y_1) \cdot f_{Y_2}(y_2) = \frac{1}{2} \cdot \frac{1}{2} \right)$ . By geometry,  $\alpha$  is the volume of the triangular wedge in the lower left-hand corner of the square over which  $Y_1$  and  $Y_2$  are defined. The hypotenuse of the triangle in the  $Y_1 Y_2$ -plane has the equation  $y_1 + y_2 = k$ . Therefore,  $\alpha = \text{area of triangle} \times \text{height of wedge} = \frac{1}{2} \cdot k \cdot k \cdot \frac{1}{4} = k^2/8$ .

For  $\alpha$  to be 0.05,  $k = \sqrt{0.4} = 0.63$ .

**6.4.22**  $\alpha = P(\text{reject } H_0 | H_0 \text{ is true}) = P(Y_1 Y_2 \leq k^* | \theta = 2)$ . If  $\theta = 2$ , the joint pdf of  $Y_1$  and  $Y_2$  is the horizontal plane  $f_{Y_1, Y_2}(y_1, y_2) = \frac{1}{4}$ ,  $0 \leq y_1 \leq 2$ ,  $0 \leq y_2 \leq 2$ . Therefore,  $\alpha = P(Y_1 Y_2 \leq k^* | \theta = 2) =$

$$2 \cdot \frac{k^*}{2} \cdot \frac{1}{4} + \int_{k^*/2}^2 \int_0^{k^*/y_1} \frac{1}{4} dy_2 dy_1 = \frac{k^*}{4} + \int_{k^*/2}^2 \frac{k^*}{4 y_1} dy_1 = \frac{k^*}{4} + \left( \frac{k^*}{4} \ln y_1 \right) \Big|_{k^*/2}^2 =$$

$$\frac{k^*}{4} + \frac{k^*}{4} \ln 2 - \frac{k^*}{4} \ln \frac{k^*}{2}. \text{ By trial and error, } k^* = 0.087 \text{ makes } \alpha = 0.05.$$

$$\text{(a) } \alpha = P(\bar{Y} \geq 1.67 | \mu = 1.6) = P\left(Z \geq \frac{1.67 - 1.6}{0.22 / \sqrt{40}}\right) = P(Z \geq 2.01) = 0.0222$$

$$\text{(b) } \beta = P(\bar{Y} < 1.67 | \mu = 1.68) = P\left(Z < \frac{1.67 - 1.68}{0.22 / \sqrt{40}}\right) = P(Z < -0.29) = 0.3859$$

**6.4.24** The cdf of  $Y_{\max}$  is  $P(Y_{\max} \leq y^* | \theta = 5) = \int_0^{y^*} \frac{6y^5}{5^6} dy = \left(\frac{y^*}{\theta}\right)^6$ . For  $\alpha = 0.05$ , choose  $y^*$ , so that

$$1 - \left(\frac{y^*}{\theta}\right)^6 = 0.05, \text{ giving } y^* = 5(0.95)^{1/6} = 4.957$$

Then the probability of a Type II error when  $\theta = 7$  is  $\beta = \left(\frac{4.957}{7}\right)^6 = 0.126$

## Section 6.5: A Notion of Optimality: The Generalized Likelihood Ratio

**6.5.1**  $L(\hat{\omega}) = \prod_{i=1}^n (1-p_0)^{k_i-1} p_0 = p_0^n (1-p_0)^{\sum_{i=1}^n k_i - n} = p_0^n (1-p_0)^{k-n}$ , where  $k = \sum_{i=1}^n k_i$ . From Case Study

5.2.1, the maximum likelihood estimate for  $p$  is  $p_e = \frac{n}{k}$ . Therefore,  $L(\hat{\Omega}) = \left(\frac{n}{k}\right)^n \left(1 - \frac{n}{k}\right)^{k-n}$ , and the generalized likelihood ratio for testing  $H_0: p = p_0$  versus  $H_1: p \neq p_0$  is the quotient  $L(\hat{\omega}) / L(\hat{\Omega})$ .

**6.5.2** Let  $y = \sum_{i=1}^{10} y_i$ . Then  $L(\hat{\omega}) = \prod_{i=1}^{10} \lambda_0 e^{-\lambda_0 y_i} = \lambda_0^{10} e^{-\lambda_0 \sum_{i=1}^{10} y_i} = \lambda_0^{10} e^{-\lambda_0 y}$ .

Also,  $L(\lambda) = \prod_{i=1}^{10} \lambda e^{-\lambda y_i} = \lambda^{10} e^{-\lambda y}$ , so  $\ln L(\lambda) = 10 \ln \lambda - \lambda y$  and  $\frac{d \ln L(\lambda)}{d \lambda} = \frac{10}{\lambda} - y$ .

Setting the latter equal to 0 implies that the maximum likelihood estimate for  $\lambda$  is  $\lambda_e = \frac{10}{y}$ .

Therefore,  $L(\hat{\Omega}) = \left(\frac{10}{y}\right)^{10} e^{-\left(\frac{10}{y}\right)y} = (10/y)^{10} e^{-10}$ . The generalized likelihood ratio, then, is the quotient  $\lambda_0^{10} e^{-\lambda_0 y} / (10/y)^{10} e^{-10} = (\lambda_0 e / 10)^{10} y^{10} e^{-\lambda_0 y}$ . It follows that  $H_0$  should be rejected if  $\lambda = y^{10} e^{-\lambda_0 y} \leq \lambda^*$ , where  $\lambda^*$  is chosen so that  $\int_0^{\lambda^*} f_\lambda(\lambda | H_0 \text{ is true}) d\lambda = 0.05$ .

**6.5.3**  $L(\hat{\omega}) = \prod_{i=1}^n (1/\sqrt{2\pi}) e^{-\frac{1}{2}(y_i - \mu_0)^2} = (2\pi)^{-n/2} e^{-\frac{1}{2} \sum_{i=1}^n (y_i - \mu_0)^2}$ . Since  $\bar{y}$  is the maximum likelihood

estimate for  $\mu$  (recall the first derivative taken in Example 5.2.4),  $L(\hat{\Omega}) = (2\pi)^{-n/2} e^{-\frac{1}{2} \sum_{i=1}^n (y_i - \bar{y})^2}$ .

Here the generalized likelihood ratio reduces to  $\lambda = L(\hat{\omega}) / L(\hat{\Omega}) = e^{-\frac{1}{2}((\bar{y} - \mu_0)/(1/\sqrt{n}))^2}$ . The null hypothesis should be rejected if  $e^{-\frac{1}{2}((\bar{y} - \mu_0)/(1/\sqrt{n}))^2} \leq \lambda^*$  or, equivalently, if  $|(\bar{y} - \mu_0)| / (1/\sqrt{n}) > \lambda^{**}$ , where values for  $\lambda^{**}$  come from the standard normal pdf,  $f_Z(z)$ .

**6.5.4** To test  $H_0: \mu = \mu_0$  versus  $H_1: \mu = \mu_1$ , the “best” critical region would consist of all those samples for which  $\prod_{i=1}^n (1/\sqrt{2\pi}) e^{-\frac{1}{2}(y_i - \mu_0)^2} / \prod_{i=1}^n (1/\sqrt{2\pi}) e^{-\frac{1}{2}(y_i - \mu_1)^2} \leq k$ . Equivalently,  $H_0$

should be rejected if  $\sum_{i=1}^n (y_i - \mu_0)^2 - \sum_{i=1}^n (y_i - \mu_1)^2 > 2 \ln k$ . Simplified, the latter becomes

$2(\mu_1 - \mu_0) \sum_{i=1}^n y_i > 2 \ln k + n(\mu_1^2 - \mu_0^2)$ . Consider the case where  $\mu_1 < \mu_0$ . Then  $\mu_1 - \mu_0 < 0$ ,

and the decision rule reduces to rejecting  $H_0$  when  $\bar{y} < \frac{2 \ln k + n(\mu_1^2 - \mu_0^2)}{2n(\mu_1 - \mu_0)}$ .

- 6.5.5** (a)  $\lambda = \left(\frac{1}{2}\right)^n / [(x/n)^x (1 - x/n)^{n-x}] = 2^{-n} x^{-x} (n-x)^{x-n} n^n$ . Rejecting  $H_0$  when  $0 < \lambda \leq \lambda^*$  is equivalent to rejecting  $H_0$  when  $x \ln x + (n-x) \ln(n-x) \geq \lambda^{**}$ .
- (b) By inspection,  $x \ln x + (n-x) \ln(n-x)$  is symmetric in  $x$ . Therefore, the left-tail and right-tail critical regions will be equidistant from  $p = \frac{1}{2}$ , which implies that  $H_0$  should be rejected if  $\left|x - \frac{1}{2}\right| \geq k$ , where  $k$  is a function of  $\alpha$ .

**6.5.6** If  $\hat{\theta}$  is a sufficient statistic for  $\theta$ , it follows from Theorem 5.6.1 that  $L(\theta) = g(\hat{\theta}; \theta) \cdot b(w_1, w_2, \dots, w_n)$ , where  $b(w_1, w_2, \dots, w_n)$  does not involve  $\theta$ . Therefore, the choice of  $\theta$  that maximizes  $L(\theta)$  is necessarily the same  $\theta$  that maximizes  $g(\hat{\theta}; \theta)$ , which, in turn, implies that the critical regions of likelihood ratio tests are functions of sufficient statistics.

# Chapter 7: Inferences Based on the Normal Distribution

## Section 7.3: Deriving the Distribution

$$\frac{\bar{Y} - \mu}{S / \sqrt{n}}$$

**7.3.1** Clearly,  $f_U(u) > 0$  for all  $u > 0$ . To verify that  $f_U(u)$  is a pdf requires proving that

$$\begin{aligned} \int_0^\infty f_U(u) du &= 1. \text{ But } \int_0^\infty f_U(u) du = \frac{1}{\Gamma(n/2)} \int_0^\infty \frac{1}{2^{n/2}} u^{n/2-1} e^{-u/2} du = \\ &= \frac{1}{\Gamma(n/2)} \int_0^\infty \left(\frac{u}{2}\right)^{n/2-1} e^{-u/2} (du/2) = \frac{1}{\Gamma\left(\frac{n}{2}\right)} \int_0^\infty v^{n/2-1} e^{-v} dv, \text{ where } v = \frac{u}{2} \text{ and } dv = \frac{du}{2}. \end{aligned}$$

By definition,  $\Gamma\left(\frac{n}{2}\right) = \int_0^\infty v^{n/2-1} e^{-v} dv$ . Thus,  $\int_0^\infty f_U(u) dy = \frac{1}{\Gamma(n/2)} \cdot \Gamma\left(\frac{n}{2}\right) = 1$ .

**7.3.2** Substituting  $\frac{n}{2}$  and  $\frac{1}{2}$  for  $r$  and  $\lambda$ , respectively, in the moment-generating function for a

gamma pdf gives  $M_{\chi_n^2}(t) = (1-2t)^{-n/2}$ . Also,  $M_{\chi_n^2}^{(1)}(t) = (-n/2) (1-2t)^{-n/2-1} (-2) =$

$n(1-2t)^{-n/2-1}$  and  $M_{\chi_n^2}^{(2)}(t) = \left(-\frac{n}{2}-1\right)(n)(1-2t)^{-n/2-2} (-2) = (n^2+2n) \cdot (1-2t)^{-n/2-2}$ , so

$M_{\chi_n^2}^{(1)}(0) = n$  and  $M_{\chi_n^2}^{(2)}(0) = n^2 + 2n$ . Therefore,  $E(\chi_n^2) = n$  and  $\text{Var}(\chi_n^2) =$

$$n^2 + 2n - n^2 = 2n.$$

**7.3.3** If  $\mu = 50$  and  $\sigma = 10$ ,  $\sum_{i=1}^3 \left(\frac{Y_i - 50}{10}\right)^2$  should have a  $\chi_3^2$  distribution, implying that the numerical value of the sum is likely to be between, say,  $\chi_{0.25,3}^2 (=0.216)$  and  $\chi_{0.975,3}^2 (=9.348)$ .

Here,  $\sum_{i=1}^3 \left( \frac{Y_i - 50}{10} \right)^2 = \left( \frac{65 - 50}{10} \right)^2 + \left( \frac{30 - 50}{10} \right)^2 + \left( \frac{55 - 50}{10} \right)^2 = 6.50$ , so the data are not inconsistent with the hypothesis that the  $Y_i$ 's are normally distributed with  $\mu = 50$  and  $\sigma = 10$ .

**7.3.4** Let  $Y = \frac{(n-1)S^2}{\sigma^2}$ . Then  $\text{Var}(Y) = \text{Var}(\chi_{n-1}^2) = 2(n-1) = \frac{(n-1)^2 \text{Var}(S^2)}{\sigma^4}$ . It follows that

$$\text{Var}(S^2) = \frac{2\sigma^4}{n-1}.$$

**7.3.5** Since  $E(S^2) = \sigma^2$ , it follows from Chebyshev's inequality that  $P(|S^2 - \sigma^2| < \varepsilon) > 1 - \frac{\text{Var}(S^2)}{\varepsilon^2}$ .

But  $\text{Var}(S^2) = \frac{2\sigma^4}{n-1} \rightarrow 0$  as  $n \rightarrow \infty$ . Therefore,  $S^2$  is consistent for  $\sigma^2$ .

**7.3.6** Let  $Y = \chi_{200}^2$ . Then  $\frac{Y-200}{\sqrt{400}} \doteq Z$ , in which case  $P\left(\frac{Y-200}{\sqrt{400}} \leq -0.25\right) \doteq 0.40$ .

Equivalently,  $Y \leq 200 - 0.25\sqrt{400} = 195$ , implying that  $\chi_{.40,200}^2 \doteq 195$ .

**7.3.7** (a) 0.983 (b) 0.132 (c) 9.00

**7.3.8**  $P\left(2.51 < \frac{V/7}{U/9} < 3.29\right) = P(2.51 < F_{7,9} < 3.29) = P(F_{7,9} < 3.29) - P(F_{7,9} \leq 2.51) = 0.95 - 0.90 = 0.05$ . But  $P(3.29 < F_{7,9} < 4.20) = 0.975 - 0.95 = 0.025$ .

**7.3.9** (a) 6.23 (b) 0.65 (c) 9 (d) 15 (e) 2.28

**7.3.10** Since the samples are independent and  $S^2/\sigma^2 = \chi_{n-1}^2/(n-1)$ , it follows that  $f_{T_n}(t) =$

$\frac{\bar{Y} - 27.6}{S/\sqrt{9}}$  has an  $F_{n-1, n-1}$  distribution. As  $n$  increases, the distributions of the unbiased

estimators  $P\left(-1.397 \leq \frac{\bar{Y} - 27.6}{S/\sqrt{9}} \leq 1.397\right)$  and  $P\left(-1.8595 \leq \frac{\bar{Y} - 27.6}{S/\sqrt{9}} \leq 1.8595\right)$  become

increasingly concentrated around  $\sigma^2$  (recall Question 7.3.4), implying that  $F$  ratios converge to 1 as the two sample sizes get large.

**7.3.11**  $F = P\left(\left|\frac{\bar{Y}-15.0}{S/\sqrt{11}}\right| \geq k\right)$ , where  $U$  and  $V$  are independent  $P\left(-k \leq \frac{\bar{Y}-15.0}{S/\sqrt{11}} \leq k\right)$  random variables with  $m$  and  $n$  degrees of freedom, respectively. Then  $\frac{\bar{Y}-15.0}{S/\sqrt{11}}$ , which implies that  $\bar{Y}$  has an  $F$  distribution with  $n$  and  $m$  degrees of freedom.

**7.3.12** If  $P(a \leq F_{m,n} \leq b) = q$ , then  $P\left(\frac{90.6 - k(S) - 90.6}{S/\sqrt{20}} \leq \frac{\bar{Y} - 90.6}{S/\sqrt{20}} \leq \frac{90.6 + k(S) - 90.6}{S/\sqrt{20}}\right)$ . From Appendix Table A.4,  $P(0.052 \leq F_{2,8} \leq 4.46) = 0.90$ . Also,  $P(0.224 \leq F_{8,2} \leq 19.4) = 0.90$ . But  $P\left(\frac{k(S)}{S/\sqrt{20}} \leq T_{19} \leq \frac{k(S)}{S/\sqrt{20}}\right) = 0.224$  and  $\frac{k(S)}{S/\sqrt{20}} = 19.23 \frac{2.8609 \cdot S}{\sqrt{20}} 19.4$ .

**7.3.13** To show that  $t_{\alpha/2, n-1} = t_{.05, 19}$  converges to  $f_Z(t)$  requires proving that  $\sum_{i=1}^{20} y_i$  converges to  $\sum_{i=1}^{20} y_i^2$

and  $\bar{y}$  converges to  $\sqrt{\frac{20(40.70) - (28.51)^2}{20(19)}}$ . To verify the first limit, write

$$\left(\bar{y} - t_{\alpha/2, n-1} \frac{s}{\sqrt{n}}, \bar{y} + t_{\alpha/2, n-1} \frac{s}{\sqrt{n}}\right) = \left(1.425 - 1.7291 \frac{0.056}{\sqrt{20}}, 1.425 + 1.7291 \frac{0.056}{\sqrt{20}}\right) =$$

$t_{\alpha/2, n-1} = t_{.025, 15}$ . As  $n$  gets large, the last factor approaches 1 and the product approaches

$\sum_{i=1}^{16} y_i$ . Also, for large  $n$ ,  $n! \bar{y}$ . Equivalently,  $\frac{1}{16}(24,256)$  if  $r$  is large. An application of

the latter equation shows that  $\left(1516.0 - 2.1314 \frac{369.02}{\sqrt{16}}, 1516.0 + 2.1314 \frac{369.02}{\sqrt{16}}\right)$  converges to

$\sum_{i=1}^{12} y_i$ , which means that the constant in  $\sum_{i=1}^{12} y_i^2$  converges to  $\bar{y} = \frac{1}{12}(425)$ , the constant in the

standard normal pdf.

**7.3.14**  $\sqrt{\frac{12(15,627) - (425)^2}{12(11)}}$  is the integral of the variable portion of a  $T_1$  pdf over the upper half of its range. Since  $\left(35.4 - 2.2010 \cdot \frac{7.2}{\sqrt{12}}, 35.4 + 2.2010 \cdot \frac{7.2}{\sqrt{12}}\right)$ , it follows that  $t_{\alpha/2, n-1} = t_{.005, 60}$ .

**7.3.15** Let  $T$  be a Student  $t$  random variable with  $n$  degrees of freedom. Then  $\bar{y} = \frac{1}{83}(8622)$ , where  $C$  is the product of the constants appearing in the definition of the Student  $t$  pdf. The change of variable  $\sqrt{\frac{83(899,750) - (8622)^2}{83(82)}}$  results in the integral  $\left(103.9 - 2.8850 \cdot \frac{7.07}{\sqrt{83}}, 103.9 + 2.8850 \cdot \frac{7.07}{\sqrt{83}}\right)$  for some constant  $C^*$ . Because of the symmetry of the integrand,  $t_{\alpha/2, n-1} = t_{.05, 23}$  is finite if the integral  $\bar{y}$  is finite.

But  $\sqrt{\frac{24(959,265) - (4645)^2}{24(23)}}$

To apply the hint, take  $\left(193.54 - 1.7139 \frac{51.19}{\sqrt{24}}, 193.54 + 1.7139 \frac{51.19}{\sqrt{24}}\right) = 2$  and

$t_{\alpha/2, n-1} = t_{.025, 15}$ . Then  $2k < n$ ,  $\left(\bar{y} - 2.1315 \cdot \frac{s}{\sqrt{16}}, \bar{y} + 2.1315 \cdot \frac{s}{\sqrt{16}}\right) > 0$ , and  $\frac{s}{\sqrt{16}} > 1$ , so

the the integral is finite.

## Section 7.4: Drawing Inferences About $\mu$

**7.4.1** (a) 0.15 (b) 0.80 (c) 0.85 (d)  $0.99 - 0.15 = 0.84$

**7.4.2** (a) 2.508 (b) -1.079 (c) 1.7056 (d) 4.3027

**7.4.3** Both differences represent intervals associated with 5% of the area under  $f_{T_n}(t)$ . Because the pdf is closer to the horizontal axis the further  $t$  is away from 0, the difference  $t_{.05, n} - t_{.10, n}$  is the larger of the two.

**7.4.4** Since  $\frac{\bar{Y} - 27.6}{S/\sqrt{9}}$  is a Student  $t$  random variable with 8 df,  $P\left(-1.397 \leq \frac{\bar{Y} - 27.6}{S/\sqrt{9}} \leq 1.397\right) = 0.80$  and  $P\left(-1.8595 \leq \frac{\bar{Y} - 27.6}{S/\sqrt{9}} \leq 1.8595\right) = 0.90$  (see Appendix Table A.2).

**7.4.5**  $P\left(\left|\frac{\bar{Y} - 15.0}{S/\sqrt{11}}\right| \geq k\right) = 0.05$  implies that  $P\left(-k \leq \frac{\bar{Y} - 15.0}{S/\sqrt{11}} \leq k\right) = 0.95$ . But  $\frac{\bar{Y} - 15.0}{S/\sqrt{11}}$  is a Student  $t$  random variable with 10 df. From Appendix Table A.2,  $P(-2.2281 \leq T_{10} \leq 2.2281) = 0.95$ , so  $k = 2.2281$ .

**7.4.6**  $P(90.6 - k(S) \leq \bar{Y} \leq 90.6 + k(S)) = 0.99 =$   
 $P\left(\frac{90.6 - k(S) - 90.6}{S/\sqrt{20}} \leq \frac{\bar{Y} - 90.6}{S/\sqrt{20}} \leq \frac{90.6 + k(S) - 90.6}{S/\sqrt{20}}\right) = P\left(\frac{k(S)}{S/\sqrt{20}} \leq T_{19} \leq \frac{k(S)}{S/\sqrt{20}}\right) =$   
 $P(-2.8609 \leq T_{19} \leq 2.8609)$ , so  $\frac{k(S)}{S/\sqrt{20}} = 2.8609$ , implying that  $k(S) = \frac{2.8609 \cdot S}{\sqrt{20}}$ .

**7.4.7** Since  $n = 20$  and the confidence interval has level 90%,  $t_{\alpha/2, n-1} = t_{.05, 19} = 1.7291$ .

For these data  $\sum_{i=1}^{20} y_i = 28.51$  and  $\sum_{i=1}^{20} y_i^2 = 40.70$ . Then  $\bar{y} = 28.51/20 = 1.425$  and

$$s = \sqrt{\frac{20(40.70) - (28.51)^2}{20(19)}} = 0.056.$$

The confidence interval is

$$\left(\bar{y} - t_{\alpha/2, n-1} \frac{s}{\sqrt{n}}, \bar{y} + t_{\alpha/2, n-1} \frac{s}{\sqrt{n}}\right) = \left(1.425 - 1.7291 \frac{0.056}{\sqrt{20}}, 1.425 + 1.7291 \frac{0.056}{\sqrt{20}}\right)$$

$$= (1.403, 1.447).$$

**7.4.8** Given that  $n = 16$  and the confidence level is 95%,  $t_{\alpha/2, n-1} = t_{.025, 15} = 2.1314$ .

Here  $\sum_{i=1}^{16} y_i = 24,256$ , so  $\bar{y} = \frac{1}{16}(24,256) = 1516.0$ , and  $s$  is given to be 369.02.

$$\text{The confidence interval is } \left(1516.0 - 2.1314 \frac{369.02}{\sqrt{16}}, 1516.0 + 2.1314 \frac{369.02}{\sqrt{16}}\right)$$

$$= (\$1319.4, \$1712.6).$$

**7.4.9** (a) Let  $\mu$  = true average age at which scientists make their greatest discoveries.

Since  $\sum_{i=1}^{12} y_i = 425$  and  $\sum_{i=1}^{12} y_i^2 = 15,627$ ,  $\bar{y} = \frac{1}{12}(425) = 35.4$  and

$$s = \sqrt{\frac{12(15,627) - (425)^2}{12(11)}} = 7.2. \quad \text{Also, } t_{\alpha/2, n-1} = t_{.025, 11} = 2.2010, \text{ so the 95\% confidence}$$

interval for  $\mu$  is the range  $\left( 35.4 - 2.2010 \cdot \frac{7.2}{\sqrt{12}}, 35.4 + 2.2010 \cdot \frac{7.2}{\sqrt{12}} \right)$ , or

(30.8 yrs, 40.0 yrs).

(b) The graph of date versus age shows no obvious patterns or trends. The assumption that  $\mu$  has remained constant over time is believable.

**7.4.10** Given that  $n = 83$  and the confidence level is 99%,  $t_{\alpha/2, n-1} = t_{.005, 60} = 2.8850$ .

$$\text{Then } \bar{y} = \frac{1}{83}(8622) = 103.9, s = \sqrt{\frac{83(899,750) - (8622)^2}{83(82)}} = 7.07$$

The 99% confidence interval for  $\mu$  is  $\left( 103.9 - 2.8850 \cdot \frac{7.07}{\sqrt{83}}, 103.9 + 2.8850 \cdot \frac{7.07}{\sqrt{83}} \right)$

= (101.6, 106.1).

**7.4.11** For  $n = 24$ ,  $t_{\alpha/2, n-1} = t_{.05, 23} = 1.7139$ . For these data  $\bar{y} = 4645/24 = 193.54$  and

$$s = \sqrt{\frac{24(959,265) - (4645)^2}{24(23)}} = 51.19.$$

The confidence interval is  $\left( 193.54 - 1.7139 \frac{51.19}{\sqrt{24}}, 193.54 + 1.7139 \frac{51.19}{\sqrt{24}} \right) = (175.6, 211.4)$ .

The medical and statistical definition of “normal” differ somewhat. There are people with medically norm platelet counts who appear in the population less than 10% of the time.

**7.4.12** Given that  $n = 16$ ,  $t_{\alpha/2, n-1} = t_{.025, 15} = 2.1315$ , so  $\left( \bar{y} - 2.1315 \cdot \frac{s}{\sqrt{16}}, \bar{y} + 2.1315 \cdot \frac{s}{\sqrt{16}} \right)$

= (44.7, 49.9). Therefore,  $49.9 - 44.7 = 5.2 = 2(2.1315) \cdot \frac{s}{\sqrt{16}}$ , implying that  $s = 4.88$ .

Also, because the confidence interval is centered around the sample mean,  $\bar{y} = \frac{44.7 + 49.9}{2} = 47.3$ .

**7.4.13** No, because the length of a confidence interval for  $\mu$  is a function of  $s$ , as well as the confidence coefficient. If the sample standard deviation for the second sample were sufficiently small (relative to the sample standard deviation for the first sample), the 95% confidence interval would be shorter than the 90% confidence interval.

**7.4.14** The range spanned by, say, a 99% confidence interval for  $\mu$  would be a reasonable set of values for the company's true average revenue. With  $n = 9$ ,  $\bar{y} = \$59,540$ , and  $s = \$6,680$ , the 99% confidence interval for  $\mu$  is  $\left( 59,540 - 3.554 \cdot \frac{6,860}{\sqrt{9}}, 59,540 + 3.554 \cdot \frac{6,860}{\sqrt{9}} \right) = (\$51,867, \$67,213)$ .

**7.4.15** (a) 0.95                      (b) 0.80                      (c) 0.945                      (d) 0.95

**7.4.16** (a) Given that  $n = 336$  and the confidence level is 95%, we use the normal tables and take

$$z_{\alpha/2} = z_{.025} = 1.96. \text{ Then } \bar{y} = \frac{1}{336}(1392.60) = 4.14, s = \sqrt{\frac{336(10,518.84) - (1392.6)^2}{336(335)}} = 3.764. \text{ Theorem 7.4.1 implies that the 95\% confidence interval for } \mu \text{ is}$$

$$\left( 4.14 - 1.96 \cdot \frac{3.764}{\sqrt{336}}, 4.14 + 1.96 \cdot \frac{3.764}{\sqrt{336}} \right) = (3.74, 4.54).$$

(b) The normality assumption is egregiously violated for these data; note that the data's histogram is sharply skewed. Theorem 7.4.1 is *not* appropriate.

**7.4.17** Let  $\mu$  = true average FEV<sub>1</sub>/VC ratio for exposed workers. Since  $\sum_{i=1}^{19} y_i = 14.56$  and  $\sum_{i=1}^{19} y_i^2 = 11.2904$ ,  $\bar{y} = \frac{14.56}{19} = 0.766$  and  $s = \sqrt{\frac{19(11.2904) - (14.56)^2}{19(18)}} = 0.0859$ .

To test  $H_0: \mu = 0.80$  versus  $H_1: \mu < 0.80$  at the  $\alpha = 0.05$  level of significance, reject the null hypothesis if  $t \leq -t_{0.05,18} = -1.7341$ . But  $t = \frac{0.766 - 0.80}{0.0859 / \sqrt{19}} = -1.71$ , so we fail to reject  $H_0$ .

**7.4.18** At the  $\alpha = 0.05$  level,  $H_0: \mu = 132.4$  should be rejected in favor of  $H_1: \mu \neq 132.4$  if

$$\left| \frac{\bar{y} - 132.4}{s / \sqrt{84}} \right| \geq t_{0.025,83} = 1.9890. \quad \text{But } t = \frac{143.8 - 132.4}{6.9 / \sqrt{84}} = 17.4, \text{ making it clear that the skull}$$

differences between Etruscans and native Italians are too great to be ascribed to chance.

A histogram of the 84  $y_i$ 's shows a distinctly bell-shaped pattern, so the normality assumption implicit in the  $t$  test appears to be satisfied.

**7.4.19** Let  $\mu$  = true average GMAT increase earned by students taking the review course. The

hypotheses to be tested are  $H_0: \mu = 40$  versus  $H_1: \mu < 40$ . Here,  $\sum_{i=1}^{15} y_i = 556$  and  $\sum_{i=1}^{15} y_i^2$

$$= 20,966, \text{ so } \bar{y} = \frac{556}{15} = 37.1, s = \sqrt{\frac{15(20,966) - (556)^2}{15(14)}} = 5.0, \text{ and } t = \frac{37.1 - 40}{5.0 / \sqrt{15}} = -2.25.$$

Since  $-t_{0.05,14} = -1.7613$ ,  $H_0$  should be rejected at the  $\alpha = 0.05$  level of significance, suggesting that the MBAs 'R Us advertisement may be fraudulent.

**7.4.20**  $H_0: \mu = 0.618$  should be rejected in favor of a two-sided  $H_1$  at the 0.01 level of significance if

$|t| \geq t_{0.005,33} = 2.7333$ . Given that  $\bar{y} = 0.6373$  and  $s = 0.14139$ , the  $t$  statistic is

$$\frac{0.6373 - 0.618}{0.14139 / \sqrt{34}} = 0.80, \text{ so } H_0 \text{ is not rejected. These data do not rule out the possibility that}$$

national flags embrace the Golden Rectangle as an aesthetic standard.

**7.4.21** Let  $u$  = true average pit depth associated with plastic coating. To test  $H_0: \mu = 0.0042$  versus

$H_1: \mu < 0.0042$  at the  $\alpha = 0.05$  level, we should reject the null hypothesis if  $t \leq -t_{0.05,9} =$

$$-1.8331. \text{ For the 10 } y_i\text{'s, } \bar{y} = \frac{0.0390}{10} = 0.0039. \text{ Also, } s = 0.000383, \text{ so } t = \frac{0.0039 - 0.0042}{0.000383 / \sqrt{10}}$$

$= -2.48$ . Since  $H_0$  is rejected, these data support the claim that the plastic coating is an effective corrosion retardant.

- 7.4.22** Let  $\mu$  = true average margin of victory. To test  $H_0: \mu = 0$  versus  $H_1: \mu > 0$  at the  $\alpha = 0.05$  level, we should reject the null hypothesis if  $t \geq z_{.05} = 1.64$ . The test statistic  $t = \frac{4.57 - 0}{18.29 / \sqrt{317}} = 4.45$ . Here  $H_0$  is rejected, so these data support the idea that the home field confers an advantage.
- 7.4.23** The set of  $\mu_0$ 's for which  $H_0: \mu = \mu_0$  would not be rejected at the  $\alpha = 0.05$  level of significance is the same as the 95% confidence interval for  $\mu$ .
- 7.4.24** Because of the skewed shape of  $f_Y(y)$ , and if the sample size was small, it would not be unusual for all the  $y_i$ 's to lie close together near 0. When that happens,  $\bar{y}$  will be less than  $\mu$ ,  $s$  will be considerably smaller than  $E(S)$ , and the  $t$  ratio will be further to the left of 0 than  $f_{T_{n-1}}(t)$  would predict.
- 7.4.25** Both sets of ratios would have distributions similar to that of a Student  $t$  random variable with 2 df. Because of the shapes of the two  $f_Y(y)$ 's, though, both distributions would be skewed to the right, particularly so for  $f_Y(y) = 4y^3$  (recall the answer to Question 7.4.23).
- 7.4.26** As  $n$  increases, Student  $t$  pdfs converge to the standard normal,  $f_Z(z)$  (see Question 7.3.13).
- 7.4.27** Only (c) would raise any serious concerns. There the sample size is small and the  $y_i$ 's are showing a markedly skewed pattern. Those are the two conditions that particularly “stress” the robustness property of the  $t$ -ratio (recall Figure 7.4.6).

Section 7.5: Drawing Inferences About  $\sigma^2$ 

7.5.1 (a) 23.685 (b) 4.605 (c) 2.700

7.5.2 (a) 0.95 (b) 0.90 (c)  $0.975 - 0.025 = 0.95$  (d) 0.99

7.5.3 (a) 2.088 (b) 7.261 (c) 14.041 (d) 17.539

7.5.4 (a) 13 (b) 19 (c) 31 (d) 17

7.5.5  $\chi_{.95,200}^2 \doteq 200 \left( 1 - \frac{2}{9(200)} + 1.64 \sqrt{\frac{2}{9(200)}} \right)^3 = 233.9$

7.5.6  $P\left(\frac{S^2}{\sigma^2} < 2\right) = P\left(\frac{(n-1)S^2}{\sigma^2} < 2(n-1)\right) = P(\chi_{n-1}^2 < 2(n-1))$ . Values from the 0.95 column in a

$\chi^2$  table show that for each  $n < 8$ ,  $P(\chi_{n-1}^2 < 2(n-1)) < 0.95$ . But for  $n = 9$ ,  $\chi_{.95,8}^2 = 15.507$ ,

which means that  $P(\chi_8^2 < 16) > 0.95$ .

7.5.7  $P\left(\chi_{\alpha/2, n-1}^2 \leq \frac{(n-1)S^2}{\sigma^2} \leq \chi_{1-\alpha/2, n-1}^2\right) = 1 - \alpha = P\left(\frac{(n-1)S^2}{\chi_{1-\alpha/2, n-1}^2} \leq \sigma^2 \leq \frac{(n-1)S^2}{\chi_{\alpha/2, n-1}^2}\right),$

so  $\left(\frac{(n-1)S^2}{\chi_{1-\alpha/2, n-1}^2}, \frac{(n-1)S^2}{\chi_{\alpha/2, n-1}^2}\right)$  is a  $100(1 - \alpha)\%$  confidence interval for  $\sigma^2$ . Taking the square root of both sides gives a  $100(1 - \alpha)\%$  confidence interval for  $\sigma$ .

7.5.8 If  $n = 19$  and  $\sigma^2 = 12.0$ ,  $\frac{18S^2}{12.0}$  has a  $\chi^2$  distribution with 18 df,

so  $P\left(8.231 \leq \frac{18S^2}{12.0} \leq 31.526\right) = 0.95 = P(5.49 \leq S^2 \leq 21.02).$

**7.5.9** (a)  $\sum_{i=1}^{16} y_i = 1514$ , so  $\bar{y} = \frac{1514}{16} = 94.6$ .  $\sum_{i=1}^{16} y_i^2 = 154,398$ , so  $s^2 = \frac{16(154,398) - (1514)^2}{16(15)}$   
 $= 742.38$ . Since  $\chi_{.025,15}^2 = 6.262$  and  $\chi_{.975,15}^2 = 27.488$ , a 95% confidence interval for  
 $\sigma$  is  $\left( \sqrt{\frac{15(742.38)}{27.488}}, \sqrt{\frac{15(742.38)}{6.262}} \right)$ , or  $(20.1, 42.2)$ .

(b) Given that  $\chi_{.05,15}^2 = 7.261$  and  $\chi_{.95,15}^2 = 24.966$ , the two one-sided confidence intervals for  
 $\sigma$  are  $\left( 0, \sqrt{\frac{15(742.38)}{7.261}} \right) = (0, 39.2)$  and  $\left( \sqrt{\frac{15(742.38)}{24.966}}, \infty \right) = (21.1, \infty)$ .

**7.5.10**  $\sum_{i=1}^{16} y_i = 29.98$ , so  $\bar{y} = \frac{29.98}{10} = 2.998$ .  $\sum_{i=1}^{16} y_i^2 = 91.609$ , so  $s^2 = \frac{10(91.609) - (29.98)^2}{10(9)}$   
 $= 0.1921$ . Since  $\chi_{.025,9}^2 = 2.700$  and  $\chi_{.975,9}^2 = 19.023$ , a 95% confidence interval for  $\sigma$  is  
 $\left( \sqrt{\frac{9(0.1921)}{19.023}}, \sqrt{\frac{9(0.1921)}{2.700}} \right) = (0.302, 0.800)$ .

Since the standard deviation for 1-year CD rates of 0.262 falls below the interval, we have evidence that the variability of 5-year CD interest rates is higher.

**7.5.11** Experimenters often prefer confidence intervals for  $\sigma$  (as opposed to  $\sigma^2$ ) because they are expressed in the same units as the data, which makes them easier to interpret.

**7.5.12** (a) If  $\frac{\chi_{n-1}^2 - (n-1)}{\sqrt{2(n-1)}} \doteq Z$ , then  $P(-z_{\alpha/2} \leq \frac{\chi_{n-1}^2 - (n-1)}{\sqrt{2(n-1)}} \leq z_{\alpha/2}) \doteq 1 - \alpha$   
 $= P\left( n-1 - z_{\alpha/2}\sqrt{2(n-1)} \leq \frac{(n-1)S^2}{\sigma^2} \leq n-1 + z_{\alpha/2}\sqrt{2(n-1)} \right)$   
 $= P\left( \frac{(n-1)S^2}{n-1 + z_{\alpha/2}\sqrt{2(n-1)}} \leq \sigma^2 \leq \frac{(n-1)S^2}{n-1 - z_{\alpha/2}\sqrt{2(n-1)}} \right)$ , so  
 $\left( \frac{(n-1)s^2}{n-1 + z_{\alpha/2}\sqrt{2(n-1)}}, \frac{(n-1)s^2}{n-1 - z_{\alpha/2}\sqrt{2(n-1)}} \right)$  is an approximate  $100(1 - \alpha)\%$  confidence  
interval for  $\sigma^2$ . Likewise,  $\left( \frac{\sqrt{n-1}s}{\sqrt{n-1 + z_{\alpha/2}\sqrt{2(n-1)}}}, \frac{\sqrt{n-1}s}{\sqrt{n-1 - z_{\alpha/2}\sqrt{2(n-1)}}} \right)$  is an  
approximate  $100(1 - \alpha)\%$  confidence interval for  $\sigma$ .

(b) For the data in Table 7.5.1,  $n = 19$  and  $s = \sqrt{733.4} = 27.08$ , so the formula in Part a gives

$$\left( \frac{\sqrt{18}(27.08)}{\sqrt{18 + 1.96\sqrt{36}}}, \frac{\sqrt{18}(27.08)}{\sqrt{18 - 1.96\sqrt{36}}} \right) = (21.1 \text{ million years}, 46.0 \text{ million years}) \text{ as the}$$

approximate 95% confidence interval for  $\sigma$ .

**7.5.13** If  $\left( \frac{(n-1)s^2}{\chi_{.95, n-1}^2}, \frac{(n-1)s^2}{\chi_{.05, n-1}^2} \right) = (51.47, 261.92)$ , then  $\chi_{.95, n-1}^2 / \chi_{.05, n-1}^2 = \frac{261.90}{51.47} = 5.088$ . A trial

and error inspection of the  $\chi^2$  table shows that  $\chi_{.95, 9}^2 / \chi_{.05, 9}^2 = \frac{16.919}{3.325} = 5.088$ , so  $n = 10$ ,

which means that  $\frac{9s^2}{3.325} = 261.92$ . Therefore,  $s = 9.8$ .

**7.5.14** (a)  $M_Y(t) = \frac{1}{1-\theta t}$ . Let  $X = \frac{2n\bar{Y}}{\theta} = \frac{2\sum_{i=1}^n Y_i}{\theta}$ . Then  $M_X(t) = \prod_{i=1}^n M_{Y_i}\left(\frac{2t}{\theta}\right) = \left(\frac{1}{1-2t}\right)^{2n/2}$ ,

implying that  $X$  is a  $\chi_{2n}^2$  random variable.

(b)  $P\left(\chi_{\alpha/2, 2n}^2 \leq \frac{2n\bar{Y}}{\theta} \leq \chi_{1-\alpha/2, 2n}^2\right) = 1 - \alpha$ , so  $\left(\frac{2n\bar{y}}{\chi_{1-\alpha/2, 2n}^2}, \frac{2n\bar{y}}{\chi_{\alpha/2, 2n}^2}\right)$  is a  $100(1 - \alpha)\%$  confidence

interval for  $\theta$ .

**7.5.15** Test  $H_0: \sigma^2 = 30.4^2$  versus  $H_1: \sigma^2 < 30.4^2$ . The test statistic in this case is

$$\chi^2 = \frac{(n-1)s^2}{\sigma_0^2} = \frac{18(733.4)}{30.4^2} = 14.285. \text{ The critical value is } \chi_{\alpha, n-1}^2 = \chi_{.05, 18}^2 = 9.390.$$

Since the test statistic is not less than the critical value, we accept the null hypothesis, and we cannot assume that the potassium-argon method is more precise.

**7.5.16** Test  $H_0: \sigma^2 = 1$  versus  $H_1: \sigma^2 > 1$

$$\text{The sample variance is } \frac{30(19,195.7938) - (758.62)^2}{30(29)} = 0.425$$

$$\text{The test statistic is } \chi^2 = \frac{29(0.425)}{1} = 12.325. \text{ The critical value is } \chi_{.95, 29}^2 = 42.557.$$

Since  $12.325 < 42.557$ , we accept the null hypothesis and assume the machine is working properly.

**7.5.17** (a) Test  $H_0 : \mu = 10.1$  versus  $H_1 : \mu > 10.1$

The test statistic is  $\frac{\bar{y} - \mu_0}{s / \sqrt{n}} = \frac{11.5 - 10.1}{10.17 / \sqrt{24}} = 0.674$

The critical value is  $t_{\alpha, n-1} = t_{0.05, 23} = 1.7139$ .

Since  $0.674 < 1.7139$ , we accept the null hypothesis. We cannot ascribe the increase of the portfolio yield over the benchmark to the analyst's system for choosing stocks.

(b) Test  $H_0 : \sigma^2 = 15.67$  versus  $H_1 : \sigma^2 < 15.67$

The test statistic is  $\chi^2 = \frac{23(10.17^2)}{15.67^2} = 9.688$ . The critical value is  $\chi_{0.05, 23}^2 = 13.091$ .

Since the test statistic of 9.688 is less than the critical value of 13.091, we reject the null hypothesis. The analyst's method of choosing stocks does seem to result in less volatility.

## Chapter 9: Two-Sample Inferences

### Section 9.2: Testing $H_0: \mu_X = \mu_Y$

9.2.1  $s_X^2 = 13.79$  and  $s_Y^2 = 15.61$

$$s_p = \sqrt{\frac{(n-1)s_X^2 + (m-1)s_Y^2}{n+m-2}} = \sqrt{\frac{11(13.79) + 8(15.61)}{12+9-2}} = 3.82$$

$$t = \frac{\bar{x} - \bar{y}}{s_p \sqrt{1/n + 1/m}} = \frac{29.8 - 26.9}{3.82 \sqrt{1/12 + 1/9}} = 1.72$$

Since  $t = 1.72 < t_{0.01,19} = 2.539$ , accept  $H_0$ .

9.2.2 For large samples, use the approximate z statistic  $z = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{s_X^2}{n} + \frac{s_Y^2}{m}}} = \frac{-4.7 - (-1.6)}{\sqrt{\frac{7.05^2}{77} + \frac{5.36^2}{79}}} = -3.09$

Since  $z = -3.09 < -1.64 = -z_{0.05}$ , reject  $H_0$ .

9.2.3 For large samples, use the approximate z statistic  $z = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{s_X^2}{n} + \frac{s_Y^2}{m}}} = \frac{189.0 - 177.2}{\sqrt{\frac{34.2^2}{476} + \frac{33.3^2}{592}}} = 5.67$

Since  $5.67 > 1.64 = z_{0.05}$ , reject  $H_0$ .

9.2.4 For large samples, use the approximate z statistic:

$$z = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{s_X^2}{n} + \frac{s_Y^2}{m}}} = \frac{10732 - 10970}{\sqrt{\frac{2017^2}{107} + \frac{1897^2}{494}}} = -1.120$$

Since  $z_{0.025} = -1.96 < -1.120 < 1.96 = z_{0.025}$ , do not reject  $H_0$ .

9.2.5 The pooled sample standard deviation is  $s_p = 3.839$ . The test statistic is

$$\frac{\bar{x} - \bar{y}}{s_p \sqrt{\frac{1}{n} + \frac{1}{m}}} = \frac{4.17 - 4.61}{3.839 \sqrt{\frac{1}{93} + \frac{1}{28}}} = -0.532$$

Since the degrees of freedom are  $93 + 28 - 2 = 119$ , use the z critical values. Then  $-z_{0.005} = -2.58 < -0.491 < 2.58 = z_{0.005}$  implies accepting  $H_0$ .

9.2.6  $t = \frac{\bar{x} - \bar{y}}{s_p \sqrt{1/n + 1/m}} = \frac{65.2 - 75.5}{13.9 \sqrt{1/9 + 1/12}} = -1.68$

Since  $-t_{0.05,19} = -1.7291 < t = -1.68$ , accept  $H_0$ .

$$\begin{aligned}
 9.2.7 \quad s_p &= s_p = \sqrt{\frac{(n-1)s_X^2 + (m-1)s_Y^2}{n+m-2}} = \sqrt{\frac{3(266.9^2) + 3(224.3^2)}{4+4-2}} = 246.52 \\
 t &= \frac{\bar{x} - \bar{y}}{s_p \sqrt{1/n + 1/m}} = \frac{1133.0 - 1013.5}{246.52 \sqrt{1/4 + 1/4}} = 0.69 \\
 \text{Since } -t_{0.025,6} &= -2.4469 < t = 0.69 < t_{0.025,6} = 2.4469, \text{ accept } H_0.
 \end{aligned}$$

$$\begin{aligned}
 9.2.8 \quad s_p &= \sqrt{\frac{5(15.1^2) + 8(8.1^2)}{6+9-2}} = 11.317 \\
 t &= \frac{70.83 - 79.33}{11.317 \sqrt{1/6 + 1/9}} = -1.43 \\
 \text{Since } -t_{0.005,13} &= -3.0123 < t = -1.43 < t_{0.005,13} = 3.0123, \text{ accept } H_0.
 \end{aligned}$$

$$\begin{aligned}
 9.2.9 \quad &\text{Test } H_0: \mu_X = \mu_Y \text{ versus } H_1: \mu_X \neq \mu_Y. \text{ Assume the variances are equal.} \\
 \text{Then } s_p &= \sqrt{\frac{48(0.96^2) + 24(1.02^2)}{49+25-2}} = 0.980 \\
 t &= \frac{2.41 - 3.00}{0.98 \sqrt{1/49 + 1/25}} = -2.45 \\
 \text{Since } t = -2.45 &< -t_{0.025,72} = -1.9935, \text{ reject } H_0.
 \end{aligned}$$

$$\begin{aligned}
 9.2.10 \quad &\text{Let } H_0: \mu_X - 1 = \mu_Y \text{ and } H_1: \mu_X - 1 < \mu_Y. \\
 s_p &= \sqrt{\frac{10(12)^2 + 10(16^2)}{10+10-2}} = 14.9 \\
 t &= \frac{(2.1-1) - 1.6}{14.9 \sqrt{1/10 + 1/10}} = -0.08 \\
 \text{Since } -t_{0.05,18} &= -1.7341 < -0.08 = t, \text{ accept } H_0.
 \end{aligned}$$

$$\begin{aligned}
 9.2.11 \quad (a) \quad &\text{Reject } H_0 \text{ if } |t| > t_{0.005,15} = 2.9467, \text{ so we seek the smallest value of } |\bar{x} - \bar{y}| \text{ such that} \\
 t &= \frac{|\bar{x} - \bar{y}|}{s_p \sqrt{1/n + 1/m}} = \frac{|\bar{x} - \bar{y}|}{15.3 \sqrt{1/6 + 1/11}} > 2.9467, \text{ or } |\bar{x} - \bar{y}| > (15.3)(0.5075)(2.9467) = \\
 &22.880
 \end{aligned}$$

$$\begin{aligned}
 (b) \quad &\text{Reject } H_0 \text{ if } t > t_{0.05,19} = 1.7291, \text{ so we seek the smallest value of } \bar{x} - \bar{y} \text{ such that} \\
 t &= \frac{\bar{x} - \bar{y}}{s_p \sqrt{1/n + 1/m}} = \frac{\bar{x} - \bar{y}}{214.9 \sqrt{1/13 + 1/8}} > 1.7291, \text{ or } \bar{x} - \bar{y} > (214.9)(0.4494)(1.7291) = \\
 &166.990
 \end{aligned}$$

$$\begin{aligned}
 9.2.12 \quad z &= \frac{\bar{x} - \bar{y}}{\sqrt{\sigma_X^2/n + \sigma_Y^2/m}} = \frac{81.6 - 79.9}{\sqrt{17.6/10 + 22.9/20}} = 1.00 \\
 \text{The } P\text{-value is } 2P(Z \geq 1.00) &= 2(1 - 0.8413) = 2(0.1587) = 0.3174
 \end{aligned}$$

**9.2.13** (a) Let  $X$  be the interstate route;  $Y$ , the town route.

$$P(Y > X) = P(X - Y > 0). \quad \text{Var}(Y - X) = \text{Var}(Y) + \text{Var}(X) = 6^2 + 5^2 = 61.$$

$$P(Y - X > 0) = P\left(\frac{Y - X - (35 - 33)}{\sqrt{61}} > \frac{2}{\sqrt{61}}\right) = P(Z \geq 0.26) = 1 - 0.6026 = 0.3974$$

(b)  $\text{Var}(\bar{X} - \bar{Y}) = \text{Var}(\bar{X}) + \text{Var}(\bar{Y}) = 6^2/10 + 5^2/10 = 61/10$

$$P(\bar{X} - \bar{Y} > 0) = P\left(\frac{\bar{X} - \bar{Y} - (33 - 35)}{\sqrt{61/10}} > \frac{2}{\sqrt{61/10}}\right) = P(Z > 0.81) = 1 - 0.7910 = 0.2090$$

**9.2.14**  $E(\bar{X} - \bar{Y}) = E(\bar{X}) - E(\bar{Y}) = \mu_X - \mu_Y$

$$\text{Var}(\bar{X} - \bar{Y}) = \text{Var}(\bar{X}) + \text{Var}(\bar{Y}) = \sigma_X^2 / n + \sigma_Y^2 / m$$

Also, we know that  $\bar{X} - \bar{Y}$  is normal. The  $Z$  variable in Equation 9.2.1 is a  $Z$  transformation of a normal variable, and thus is standard normal.

**9.2.15** It follows from Example 5.4.4 that  $E(S_X^2) = E(S_Y^2) = \sigma^2$ .

$$E(S_p^2) = \frac{(n-1)E(S_X^2) + (m-1)E(S_Y^2)}{n+m-2} = \frac{(n-1)\sigma^2 + (m-1)\sigma^2}{n+m-2} = \sigma^2$$

**9.2.16** Take  $\omega = \{(\mu_X, \mu_Y): -\infty < \mu_X = \mu_Y < \infty\}$ . Since the  $X$ 's and  $Y$ 's are normal and independent,

$$L(\omega) = \prod_{i=1}^n f_X(x_i) \prod_{i=1}^m f_Y(y_i) = \left(\frac{1}{\sqrt{2\pi}\sigma}\right)^{n+m} \exp\left[-\frac{1}{2\sigma^2}\left(\sum_{i=1}^n (x_i - \mu)^2 + \sum_{i=1}^m (y_i - \mu)^2\right)\right],$$

where  $\mu = \mu_X = \mu_Y$ . Differentiating the expression with respect to  $\mu$  and setting it equal to 0

yields the maximum likelihood estimate  $\hat{\mu} = \frac{\sum_{i=1}^n x_i + \sum_{i=1}^m y_i}{n+m} = \frac{n\bar{x} + m\bar{y}}{n+m}$ . Substituting  $\hat{\mu}$  for  $\mu$  in

$L(\omega)$  gives the numerator of the generalized likelihood ratio. After algebraic simplification,

$$\text{we obtain } L(\hat{\omega}) = \left(\frac{1}{\sqrt{2\pi}\sigma}\right)^{n+m} \exp\left[-\frac{1}{2\sigma^2}\left(\sum_{i=1}^n x_i^2 + \sum_{i=1}^m y_i^2 - \frac{(n\bar{x} + m\bar{y})^2}{n+m}\right)\right].$$

The likelihood function unrestricted by the null hypothesis is

$$L(\Omega) = \left(\frac{1}{\sqrt{2\pi}\sigma}\right)^{n+m} \exp\left[-\frac{1}{2\sigma^2}\left(\sum_{i=1}^n (x_i - \mu_X)^2 + \sum_{i=1}^m (y_i - \mu_Y)^2\right)\right]$$

Solving  $\frac{\partial \ln L(\Omega)}{\partial \mu_X} = 0$  and  $\frac{\partial \ln L(\Omega)}{\partial \mu_Y} = 0$  gives  $\hat{\mu}_X = \bar{x}$  and  $\hat{\mu}_Y = \bar{y}$ . Substituting those

values into  $L(\Omega)$  gives  $L(\hat{\Omega})$ , which simplifies to

$$L(\hat{\Omega}) = \left(\frac{1}{\sqrt{2\pi}\sigma}\right)^{n+m} \exp\left[-\frac{1}{2\sigma^2}\left(\sum_{i=1}^n x_i^2 - n\bar{x}^2 + \sum_{i=1}^m y_i^2 - m\bar{y}^2\right)\right]$$

$$\lambda = \frac{L(\hat{\omega})}{L(\hat{\Omega})} = \exp\left[-\frac{1}{2\sigma^2}\left(n\bar{x}^2 + m\bar{y}^2 - \frac{(n\bar{x} + m\bar{y})^2}{n+m}\right)\right] = \exp\left[-\frac{1}{2\sigma^2}\left(\frac{nm(\bar{x} - \bar{y})^2}{n+m}\right)\right].$$

Rejecting  $H_0$  when  $0 < \lambda < \lambda^*$  is equivalent to  $\ln \lambda < \ln \lambda^*$  or  $-2\ln \lambda > -2\ln \lambda^* = \lambda^{**}$ . But  $-2\ln \lambda = \frac{(\bar{x} - \bar{y})^2}{\sigma^2 \left( \frac{1}{n} + \frac{1}{m} \right)}$ . Thus, we reject  $H_0$  when  $\frac{\bar{x} - \bar{y}}{\sigma \sqrt{\frac{1}{n} + \frac{1}{m}}} < -\sqrt{\lambda^{**}}$  or  $\frac{\bar{x} - \bar{y}}{\sigma \sqrt{\frac{1}{n} + \frac{1}{m}}} > \sqrt{\lambda^{**}}$ ,

and we recognize this as a  $Z$  test when  $\sigma^2$  is known.

**9.2.17** For the data given,  $\bar{x} = 545.45$ ,  $s_X = 428$ , and  $\bar{y} = 241.82$ ,  $s_Y = 183$ . Then

$$t = \frac{\bar{x} - \bar{y}}{\sqrt{s_X^2/n + s_Y^2/m}} = \frac{545.45 - 241.82}{\sqrt{428^2/11 + 183^2/11}} = 2.16$$

Let  $\hat{\theta} = \frac{s_X^2}{s_Y^2} = \frac{428^2}{183^2} = 5.47$ . The degrees of freedom associated with this statistic is greatest

$$\text{integer in } \nu = \frac{\left( \hat{\theta} + \frac{n}{m} \right)^2}{\frac{1}{(n-1)}\hat{\theta}^2 + \frac{1}{(m-1)}\left( \frac{n}{m} \right)^2} = \frac{\left( 5.47 + \frac{11}{11} \right)^2}{\frac{1}{(11-1)}(5.47)^2 + \frac{1}{(11-1)}\left( \frac{11}{11} \right)^2} = 13.5$$

Thus, the greatest integer is 13. Since  $t = 2.16 > t_{0.05,13} = 1.7709$ , reject  $H_0$ .

**9.2.18** Decreasing the degrees of freedom also decreases the power of the test.

- 9.2.19** (a) The sample standard deviation for the first data set is approximately 3.15; for the second, 3.29. These values seem close enough to permit the use of Theorem 9.2.2.  
 (b) Intuitively, the states with the comprehensive law should have fewer deaths. However, the average for these data is 8.1, which is larger than the average of 7.0 for the states with a more limited law.

**9.2.20** Test  $H_0: \mu_X = \mu_Y$  versus  $H_1: \mu_X > \mu_Y$ . For the data given,  $\bar{x} = 3.67$ ,  $s_X^2 = 0.024$ , and  $\bar{y} = 3.34$ ,

$$s_Y^2 = 0.047. \text{ Then } t = \frac{\bar{x} - \bar{y}}{\sqrt{s_X^2/n + s_Y^2/m}} = \frac{3.67 - 3.34}{\sqrt{0.024/10 + 0.047/10}} = 3.994$$

Let  $\hat{\theta} = \frac{s_X^2}{s_Y^2} = \frac{0.024}{0.047} = 0.511$ . The degrees of freedom associated with this statistic is the

$$\text{greatest integer in } \nu = \frac{\left( 0.511 + \frac{10}{10} \right)^2}{\frac{1}{(10-1)}(0.511)^2 + \frac{1}{(10-1)}\left( \frac{10}{10} \right)^2} = 16.29, \text{ that is, } 16$$

Since  $t = 3.994 > t_{0.01,16} = 2.583$ , reject  $H_0$ .

## Section 9.3: Testing $H_0: \sigma_X^2 = \sigma_Y^2$ —The $F$ Test

**9.3.1** From the case study,  $s_X^2 = 115.9929$  and  $s_Y^2 = 35.7604$ . The observed

$F = \frac{35.7604}{115.9929} = 0.308$ . Since  $F_{.025,11,11} = 0.288 < 0.308 < 3.47 = F_{.975,11,11}$ , we can assume that the variances are equal.

- 9.3.2** The observed  $F = 0.047/0.024 = 1.958$ . Since  $F_{.90,9,9} = 2.44$ , we do not reject  $H_0$  that the variances are equal.
- 9.3.3** (a) The critical values are  $F_{.025,19,19}$  and  $F_{.975,19,19}$ . These values are not tabulated, but in this case, we can approximate them by  $F_{.025,20,20} = 0.406$  and  $F_{.975,20,20} = 2.46$ . The observed  $F = 2.41/3.52 = 0.685$ . Since  $0.406 < 0.685 < 2.46$ , we can assume that the variances are equal.  
 (b) Since  $t = 2.662 > t_{.025,38} = 2.0244$ , reject  $H_0$ .
- 9.3.4** The observed  $F = \frac{3.18^2}{5.67^2} = \frac{10.1124}{32.1489} = 0.315$ . Since  $F_{.025,9,9} = 0.248 < 0.315 < 4.03 = F_{.975,9,9}$ , we can accept  $H_0$  that the variances are equal.
- 9.3.5**  $F = 0.20^2/0.37^2 = 0.292$ . Since  $F_{.025,9,9} = 0.248 < 0.292 < 4.03 = F_{.975,9,9}$ , accept  $H_0$ .
- 9.3.6** The observed  $F = 398.75/274.52 = 1.453$ . Let  $\alpha = 0.05$ . The critical values are  $F_{.025,13,11}$  and  $F_{.975,13,11}$ . These values are not in Table A.4, so approximate them by  $F_{.025,12,11} = 0.301$  and  $F_{.975,12,11} = 3.47$ . Since  $0.301 < 1.453 < 3.47$ , accept  $H_0$  that the variances are equal. Theorem 9.2.2 is appropriate.
- 9.3.7** Let  $\alpha = 0.05$ .  $F = 65.25/227.77 = 0.286$ . Since  $F_{.025,8,5} = 0.208 < 0.286 < 6.76 = F_{.975,8,5}$ , accept  $H_0$ . Thus, Theorem 9.2.2 is appropriate.
- 9.3.8** For these data,  $s_X^2 = 56.86$  and  $s_Y^2 = 66.5$ . The observed  $F = 66.5/56.86 = 1.170$ . Since  $F_{.025,8,8} = 0.226 < 1.170 < 4.43 = F_{.975,8,8}$ , we can accept  $H_0$  that the variances are equal. Thus, Theorem 9.2.2 can be used, as it has the hypothesis that the variances are equal.

- 9.3.9** If  $\sigma_X^2 = \sigma_Y^2 = \sigma^2$ , the maximum likelihood estimator for  $\sigma^2$  is

$$\hat{\sigma}^2 = \frac{1}{n+m} \left( \sum_{i=1}^n (x_i - \bar{x})^2 + \sum_{i=1}^m (y_i - \bar{y})^2 \right).$$

$$\text{Then } L(\hat{\omega}) = \left( \frac{1}{2\pi\hat{\sigma}^2} \right)^{(n+m)/2} e^{-\frac{1}{2\hat{\sigma}^2} \left( \sum_{i=1}^n (x_i - \bar{x})^2 + \sum_{i=1}^m (y_i - \bar{y})^2 \right)} = \left( \frac{1}{2\pi\hat{\sigma}^2} \right)^{(n+m)/2} e^{-(n+m)/2}$$

If  $\sigma_X^2 \neq \sigma_Y^2$  the maximum likelihood estimators for  $\sigma_X^2$  and  $\sigma_Y^2$  are  $\hat{\sigma}_X^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2$

$$\text{and } \hat{\sigma}_Y^2 = \frac{1}{m} \sum_{i=1}^m (y_i - \bar{y})^2.$$

$$\text{Then } L(\hat{\Omega}) = \left( \frac{1}{2\pi\hat{\sigma}_X^2} \right)^{n/2} e^{-\frac{1}{2\hat{\sigma}_X^2} \left( \sum_{i=1}^n (x_i - \bar{x})^2 \right)} \left( \frac{1}{2\pi\hat{\sigma}_Y^2} \right)^{m/2} e^{-\frac{1}{2\hat{\sigma}_Y^2} \left( \sum_{i=1}^m (y_i - \bar{y})^2 \right)} =$$

$$\left( \frac{1}{2\pi\hat{\sigma}_X^2} \right)^{n/2} e^{-n/2} \left( \frac{1}{2\pi\hat{\sigma}_Y^2} \right)^{m/2} e^{-m/2}$$

The ratio  $\lambda = \frac{L(\hat{\omega})}{L(\hat{\Omega})} = \frac{(\hat{\sigma}_X^2)^{n/2} (\hat{\sigma}_Y^2)^{m/2}}{(\hat{\sigma}^2)^{(n+m)/2}}$  equates to the expression given in the statement of the question.

- 9.3.10** Since  $\mu_X$  and  $\mu_Y$  are known, the maximum likelihood estimator uses  $\mu_X$  instead of  $\bar{x}$  and  $\mu_Y$  instead of  $\bar{y}$ . For the GLRT,  $\lambda$  is as in Question 9.3.9 with those substitutions.

## Section 9.4: Binomial Data: Testing $H_0: p_X = p_Y$

**9.4.1** 
$$p_e = \frac{x+y}{n+m} = \frac{55+40}{200+200} = 0.2375$$

$$z = \frac{\frac{x}{n} - \frac{y}{m}}{\sqrt{\frac{\hat{p}(1-\hat{p})}{n} + \frac{\hat{p}(1-\hat{p})}{m}}} = \frac{\frac{55}{200} - \frac{40}{200}}{\sqrt{\frac{0.2375(0.7625)}{200} + \frac{0.2375(0.7625)}{200}}} = 1.76$$

Since  $-1.96 < z = 1.76 < 1.96 = z_{.025}$ , accept  $H_0$ .

**9.4.2** 
$$p_e = \frac{x+y}{n+m} = \frac{66+93}{423+423} = 0.188$$

$$z = \frac{\frac{x}{n} - \frac{y}{m}}{\sqrt{\frac{\hat{p}(1-\hat{p})}{n} + \frac{\hat{p}(1-\hat{p})}{m}}} = \frac{\frac{66}{423} - \frac{93}{423}}{\sqrt{\frac{0.188(0.812)}{423} + \frac{0.188(0.812)}{423}}} = -2.38$$

For this experiment,  $H_0: p_X = p_Y$  and  $H_1: p_X < p_Y$ . Since  $z = -2.38 < -1.64 = -z_{.05}$ , reject  $H_0$ .

**9.4.3** Let  $\alpha = 0.05$ . 
$$p_e = \frac{24+27}{29+32} = 0.836$$

$$z = \frac{\frac{24}{29} - \frac{27}{32}}{\sqrt{\frac{0.836(0.164)}{29} + \frac{0.836(0.164)}{32}}} = -0.17$$

For this experiment,  $H_0: p_X = p_Y$  and  $H_1: p_X \neq p_Y$ . Since  $-1.96 < z = -0.17 < 1.96 = z_{.025}$ , accept  $H_0$  at the 0.05 level of significance.

**9.4.4** 
$$p_e = \frac{53+705}{91+1117} = 0.627$$

$$z = \frac{\frac{53}{91} - \frac{705}{1117}}{\sqrt{\frac{0.627(0.373)}{91} + \frac{0.627(0.373)}{1117}}} = -0.92$$

Since  $-2.58 < z = -0.92 < 2.58 = z_{.005}$ , accept  $H_0$  at the 0.01 level of significance.

$$9.4.5 \quad p_e = \frac{1033 + 344}{1675 + 660} = 0.590$$

$$z = \frac{0.617 - 0.521}{\sqrt{\frac{0.590(0.410)}{1675} + \frac{0.590(0.410)}{660}}} = 4.25$$

Since  $z = 4.25 > 2.33 = z_{.01}$ , reject  $H_0$  at the 0.01 level of significance.

$$9.4.6 \quad p_e = \frac{60 + 48}{100 + 100} = 0.54$$

$$z = \frac{\frac{60}{100} - \frac{48}{100}}{\sqrt{\frac{0.54(0.46)}{100} + \frac{0.54(0.46)}{100}}} = 1.70$$

The  $P$  value is  $P(Z \leq -1.70) + P(Z \geq 1.70) = 2(1 - 0.9554) = 0.0892$ .

$$9.4.7 \quad p_e = \frac{2915 + 3086}{4134 + 4471} = 0.697$$

$$z = \frac{\frac{2915}{4134} - \frac{3086}{4471}}{\sqrt{\frac{0.697(0.303)}{4134} + \frac{0.697(0.303)}{4471}}} = 1.50$$

Since  $-1.96 < z = 1.50 < 1.96 = z_{.025}$ , accept  $H_0$  at the 0.05 level of significance.

$$9.4.8 \quad p_e = \frac{175 + 100}{609 + 160} = 0.358$$

$$z = \frac{\frac{175}{609} - \frac{100}{160}}{\sqrt{\frac{0.358(0.642)}{609} + \frac{0.358(0.642)}{160}}} = -7.93. \text{ Since } z = -7.93 < -1.96 = -z_{.025}, \text{ reject } H_0.$$

$$9.4.9 \quad p_e = \frac{78 + 50}{300 + 200} = 0.256$$

$$z = \frac{\frac{78}{300} - \frac{50}{200}}{\sqrt{\frac{0.256(0.744)}{300} + \frac{0.256(0.744)}{200}}} = 0.25. \text{ In this situation, } H_1 \text{ is } p_X > p_Y.$$

Since  $z = 0.25 < 1.64 = z_{.05}$ , accept  $H_0$ . The player is right.

$$9.4.10 \quad \text{From Equation 9.4.1, } \lambda = \frac{[(55 + 60) / (160 + 192)]^{(55+60)} [1 - (55 + 60) / (160 + 192)]^{(160+192-55-60)}}{(55 / 160)^{55} [1 - (55 / 160)]^{105} (60 / 192)^{60} [1 - (60 / 192)]^{132}}$$

$$= \frac{115^{115} (237^{237}) (160^{160}) (192^{192})}{352^{352} (55^{55}) (105^{105}) (60^{60}) (132^{132})}. \text{ We calculate } \ln \lambda, \text{ which is } -0.1935.$$

Then  $-2 \ln \lambda = 0.387$ . Since  $-2 \ln \lambda = 0.387 < 6.635 = \chi_{.99,1}^2$ , accept  $H_0$ .

## Section 9.5: Confidence Intervals for the Two-Sample Problem

**9.5.1** The center of the confidence interval is  $\bar{x} - \bar{y} = 6.7 - 5.6 = 1.1$ .  $s_p = \sqrt{\frac{8(0.54^2) + 6(0.36^2)}{14}} =$

0.47. The radius is  $t_{\alpha/2, n+m-2} s_p \sqrt{\frac{1}{n} + \frac{1}{m}} = 1.7613(0.47) \sqrt{\frac{1}{9} + \frac{1}{7}} = 0.42$ . The confidence interval is  $(1.1 - 0.42, 1.1 + 0.42) = (0.68, 1.52)$ . Since 0 is not in the interval, we can reject the null hypothesis that  $\mu_X = \mu_Y$ .

**9.5.2** The center of the confidence interval is  $\bar{x} - \bar{y} = 83.96 - 84.84 = -0.88$ . The radius is

$t_{\alpha/2, n+m-2} s_p \sqrt{\frac{1}{n} + \frac{1}{m}} = 2.2281(11.2) \sqrt{\frac{1}{5} + \frac{1}{7}} = 14.61$ . The confidence interval is  $(-0.88 - 14.61, -0.88 + 14.61) = (-15.49, 13.73)$ . Since the confidence interval contains 0, the data do not suggest that the dome makes a difference.

**9.5.3** In either case, the center of the confidence interval is  $\bar{x} - \bar{y} = 18.6 - 21.9 = -3.3$ . For the

assumption of equal variances, calculate  $s_p = \sqrt{\frac{11(115.9929) + 11(35.7604)}{22}} = 8.71$

The radius of the interval is  $t_{.005, 22} s_p \sqrt{\frac{1}{12} + \frac{1}{12}} = 2.8188(8.71) \sqrt{\frac{1}{12} + \frac{1}{12}} = 10.02$

The confidence interval is  $(-3.3 - 10.02, -3.3 + 10.02) = (-13.32, 6.72)$ .

For the case of unequal variances, the radius of the interval is

$t_{.005, 17} \sqrt{\frac{s_X^2}{12} + \frac{s_Y^2}{12}} = 2.8982 \sqrt{\frac{115.9929}{12} + \frac{35.7604}{12}} = 10.31$

The confidence interval is  $(-3.3 - 10.31, -3.3 + 10.31) = (-13.61, 7.01)$ .

**9.5.4** Equation (9.5.1) is  $P \left( -t_{\alpha/2, n+m-2} \leq \frac{\bar{X} - \bar{Y} - (\mu_X - \mu_Y)}{S_p \sqrt{\frac{1}{n} + \frac{1}{m}}} \leq t_{\alpha/2, n+m-2} \right) = 1 - \alpha$  so

$P \left( -t_{\alpha/2, n+m-2} S_p \sqrt{\frac{1}{n} + \frac{1}{m}} \leq \bar{X} - \bar{Y} - (\mu_X - \mu_Y) \leq t_{\alpha/2, n+m-2} S_p \sqrt{\frac{1}{n} + \frac{1}{m}} \right) = 1 - \alpha$ , or

$P \left( -(\bar{X} - \bar{Y}) - t_{\alpha/2, n+m-2} S_p \sqrt{\frac{1}{n} + \frac{1}{m}} \leq -(\mu_X - \mu_Y) \leq -(\bar{X} - \bar{Y}) + t_{\alpha/2, n+m-2} S_p \sqrt{\frac{1}{n} + \frac{1}{m}} \right) = 1 - \alpha$ .

Multiplying the inequality above by  $-1$  gives the inequality of the confidence interval of Theorem 9.5.1.

**9.5.5** Begin with the statistic  $\bar{X} - \bar{Y}$ , which has  $E(\bar{X} - \bar{Y}) = \mu_X - \mu_Y$  and  $\text{Var}(\bar{X} - \bar{Y}) = \sigma_X^2/n + \sigma_Y^2/m$ . Then  $P\left(-z_{\alpha/2} \leq \frac{\bar{X} - \bar{Y} - (\mu_X - \mu_Y)}{\sqrt{\sigma_X^2/n + \sigma_Y^2/m}} \leq z_{\alpha/2}\right) = 1 - \alpha$ , which implies

$$P\left(-z_{\alpha/2}\sqrt{\sigma_X^2/n + \sigma_Y^2/m} \leq \bar{X} - \bar{Y} - (\mu_X - \mu_Y) \leq z_{\alpha/2}\sqrt{\sigma_X^2/n + \sigma_Y^2/m}\right) = 1 - \alpha.$$

Solving the inequality for  $\mu_X - \mu_Y$  gives

$$P\left(\bar{X} - \bar{Y} - z_{\alpha/2}\sqrt{\sigma_X^2/n + \sigma_Y^2/m} \leq \mu_X - \mu_Y \leq \bar{X} - \bar{Y} + z_{\alpha/2}\sqrt{\sigma_X^2/n + \sigma_Y^2/m}\right) = 1 - \alpha. \text{ Thus}$$

the confidence interval is  $\left(\bar{x} - \bar{y} - z_{\alpha/2}\sqrt{\sigma_X^2/n + \sigma_Y^2/m}, \bar{x} - \bar{y} + z_{\alpha/2}\sqrt{\sigma_X^2/n + \sigma_Y^2/m}\right)$ .

**9.5.6** The observed ratio is  $F = \frac{s_X^2}{s_Y^2} = \frac{0.0002103}{0.0000955} = 2.20$ . The confidence interval is

$$\left(\frac{s_X^2}{s_Y^2} F_{0.025, 9, 7}, \frac{s_X^2}{s_Y^2} F_{0.975, 9, 7}\right) = (0.238(2.20), 4.82(2.20)) = (0.52, 10.60). \text{ Because the}$$

confidence interval contains 1, it supports the assumption of Case Study 9.2.1 that the variances are equal.

**9.5.7** The confidence interval is  $\left(\frac{s_X^2}{s_Y^2} F_{0.025, 5, 7}, \frac{s_X^2}{s_Y^2} F_{0.975, 5, 7}\right) = \left(\frac{137.4}{340.3}(0.146), \frac{137.4}{340.3}(5.29)\right) = (0.06, 2.14)$ . Since the confidence interval contains 1, we can accept  $H_0$  that the variances are equal, and Theorem 9.2.1 applies.

**9.5.8** Since  $\frac{S_Y^2/\sigma_Y^2}{S_X^2/\sigma_X^2}$  has an  $F$  distribution with  $m - 1$  and  $n - 1$  degrees of freedom,

$$P\left(F_{\alpha/2, m-1, n-1} \leq \frac{S_Y^2/\sigma_Y^2}{S_X^2/\sigma_X^2} \leq F_{1-\alpha/2, m-1, n-1}\right) = P\left(\frac{S_X^2}{S_Y^2} F_{\alpha/2, m-1, n-1} \leq \frac{\sigma_X^2}{\sigma_Y^2} \leq \frac{S_X^2}{S_Y^2} F_{1-\alpha/2, m-1, n-1}\right) = 1 - \alpha.$$

The inequality provides the confidence interval of Theorem 9.5.2.

**9.5.9** The center of the confidence interval is  $\frac{x}{n} - \frac{y}{m} = \frac{126}{782} - \frac{111}{758} = 0.015$ . The radius is

$$z_{0.025} \sqrt{\frac{\left(\frac{x}{n}\right)\left(1 - \frac{x}{n}\right)}{n} + \frac{\left(\frac{y}{m}\right)\left(1 - \frac{y}{m}\right)}{m}} = 1.96 \sqrt{\frac{\left(\frac{126}{782}\right)\left(1 - \frac{126}{782}\right)}{782} + \frac{\left(\frac{111}{758}\right)\left(1 - \frac{111}{758}\right)}{758}} = 0.036.$$

The 95% confidence interval is  $(0.015 - 0.036, 0.015 + 0.036) = (-0.021, 0.051)$

Since 0 is in the confidence interval, one cannot conclude a significantly different frequency of headaches.

**9.5.10** The center of the confidence interval is  $\frac{x}{n} - \frac{y}{m} = \frac{55}{160} - \frac{60}{192} = 0.031$ . The radius is

$$z_{0.10} \sqrt{\frac{\left(\frac{x}{n}\right)\left(1 - \frac{x}{n}\right)}{n} + \frac{\left(\frac{y}{m}\right)\left(1 - \frac{y}{m}\right)}{m}} = 1.28 \sqrt{\frac{\left(\frac{55}{160}\right)\left(1 - \frac{55}{160}\right)}{160} + \frac{\left(\frac{60}{192}\right)\left(1 - \frac{60}{192}\right)}{192}} = 0.064.$$

The 80% confidence interval is  $(0.031 - 0.064, 0.031 + 0.064) = (-0.033, 0.095)$

**9.5.11** The approximate normal distribution implies that

$$P\left(-z_\alpha \leq \frac{\frac{X}{n} - \frac{Y}{m} - (p_X - p_Y)}{\sqrt{\frac{(X/n)(1-X/n)}{n} + \frac{(Y/m)(1-Y/m)}{m}}} \leq z_\alpha\right) = 1 - \alpha$$

or  $P\left(-z_\alpha \sqrt{\frac{(X/n)(1-X/n)}{n} + \frac{(Y/m)(1-Y/m)}{m}} \leq \frac{X}{n} - \frac{Y}{m} - (p_X - p_Y) \leq z_\alpha \sqrt{\frac{(X/n)(1-X/n)}{n} + \frac{(Y/m)(1-Y/m)}{m}}\right) = 1 - \alpha$  which implies that

$$P\left(-\left(\frac{X}{n} - \frac{Y}{m}\right) - z_\alpha \sqrt{\frac{(X/n)(1-X/n)}{n} + \frac{(Y/m)(1-Y/m)}{m}} \leq -(p_X - p_Y) \leq -\left(\frac{X}{n} - \frac{Y}{m}\right) + z_\alpha \sqrt{\frac{(X/n)(1-X/n)}{n} + \frac{(Y/m)(1-Y/m)}{m}}\right) = 1 - \alpha$$

Multiplying the inequality by  $-1$  yields the confidence interval.

**9.5.12** The center of the confidence interval is  $\frac{x}{n} - \frac{y}{m} = \frac{9}{77} - \frac{6}{73} = 0.035$ . The radius is

$$z_{.025} \sqrt{\frac{\left(\frac{x}{n}\right)\left(1 - \frac{x}{n}\right)}{n} + \frac{\left(\frac{y}{m}\right)\left(1 - \frac{y}{m}\right)}{m}} = 1.96 \sqrt{\frac{\left(\frac{9}{77}\right)\left(1 - \frac{9}{77}\right)}{77} + \frac{\left(\frac{6}{73}\right)\left(1 - \frac{6}{73}\right)}{73}} = 0.096$$

The 95% confidence interval is  $(0.035 - 0.096, 0.035 + 0.096) = (-0.061, 0.131)$ . Since the confidence interval contains 0, there is not statistical evidence that the two methods differ in complication rates.

# Chapter 10: Goodness-of-Fit Tests

## Section 10.2: The Multinomial Distribution

**10.2.1** Let  $X_i$  = number of students with a score of  $i$ ,  $i = 1, 2, 3, 4, 5$ . Then  $P(X_1 = 0, X_2 = 0, X_3 = 1, X_4 = 2, X_5 = 3) = \frac{6!}{1!2!3!} (0.185)^1 (0.169)^2 (0.446)^3 = 0.0281$

**10.2.2** Let  $X_1$  = number of round and yellow phenotypes,  $X_2$  = number of round and green phenotypes, and so on.

$$\text{Then } P(X_1 = 1, X_2 = 1, X_3 = 1, X_4 = 1) = \frac{4!}{1!1!1!1!} \left(\frac{9}{16}\right)^1 \left(\frac{3}{16}\right)^1 \left(\frac{3}{16}\right)^1 \left(\frac{1}{16}\right)^1 = 0.0297.$$

**10.2.3** Let  $Y$  denote a person's blood pressure and let  $X_1, X_2$ , and  $X_3$  denote the number of individuals with blood pressures less than 140, between 140 and 160, and over 160, respectively. If  $\mu = 124$  and  $\sigma = 13.7$ ,  $p_1 = P(Y < 140) = P\left(Z < \frac{140-124}{13.7}\right) = 0.8790$ ,

$$p_2 = P(140 \leq Y \leq 160) = P\left(\frac{140-124}{13.7} \leq Z \leq \frac{160-124}{13.7}\right) = 0.1167, \text{ and } p_3 = 1 - p_1 - p_2 =$$

$$0.0043. \text{ Then } P(X_1 = 6, X_2 = 3, X_3 = 1) = \frac{10!}{6!3!1!} (0.8790)^6 (0.1167)^3 (0.0043)^1 = 0.00265.$$

**10.2.4** Let  $Y$  denote a recruit's IQ and let  $X_i$  denote the number of recruits in class  $i$ ,  $i = 1, 2, 3$ . Then  $p_1 = P(\text{class I}) = P(Y < 90) = P\left(Z < \frac{90-100}{16}\right) = 0.2643$ ,  $p_2 = P(\text{class II}) = P(90 \leq Y \leq 110) =$

$$P\left(\frac{90-100}{16} \leq Z \leq \frac{110-100}{16}\right) = 0.4714, \text{ and } p_3 = P(\text{class III}) = P(Y > 110) = 1 - p_1 - p_2 =$$

$$0.2643. \text{ From Theorem 10.2.1, } P(X_1 = 2, X_2 = 4, X_3 = 1) = \frac{7!}{2!4!1!} (0.2643)^2 (0.4714)^4 (0.2643)^1 = 0.0957.$$

**10.2.5** Let  $Y$  denote the distance between the pipeline and the point of impact. Let  $X_1$  denote the number of missiles landing within 20 yards to the left of the pipeline, let  $X_2$  denote the number of missiles landing within 20 yards to the right of the pipeline, and let  $X_3$  denote the number of missiles for which  $|y| > 20$ . By the symmetry of  $f_Y(y)$ ,  $p_1 = P(-20 \leq Y \leq 0) = \frac{5}{18} =$

$$P(0 \leq Y \leq 20) = p_2, \text{ so } p_3 = P(|Y| > 20) = 1 - \frac{5}{18} - \frac{5}{18} = \frac{8}{18}.$$

$$\text{Therefore, } P(X_1 = 2, X_2 = 4, X_3 = 0) = \frac{6!}{2!4!0!} \left(\frac{5}{18}\right)^2 \left(\frac{5}{18}\right)^4 \left(\frac{8}{18}\right)^0 = 0.00689.$$

**10.2.6** Let  $X_i$ ,  $i = 1, 2, 3, 4, 5$ , denote the number of outs, singles, doubles, triples, and home runs, respectively, that the player makes in 5 at-bats. Then  $P(\text{two-outs, two singles, one double})$

$$= P(X_1 = 2, X_2 = 2, X_3 = 1, X_4 = 0, X_5 = 0) = \frac{5!}{2!2!1!0!0!} \cdot (0.713)^2(0.270)^2(0.010)^1(0.002)^0(0.005)^0 = 0.0111.$$

**10.2.7** (a)  $p_1 = P\left(0 \leq Y < \frac{1}{4}\right) = \int_0^{1/4} 3y^2 dy = \frac{1}{64}$ ,  $p_2 = P\left(\frac{1}{4} \leq Y < \frac{1}{2}\right) = \int_{1/4}^{1/2} 3y^2 dy = \frac{7}{64}$ ,  
 $p_3 = P\left(\frac{1}{2} \leq Y < \frac{3}{4}\right) = \int_{1/2}^{3/4} 3y^2 dy = \frac{19}{64}$ , and  $p_4 = P\left(\frac{3}{4} \leq Y \leq 1\right) = \int_{3/4}^1 3y^2 dy = \frac{37}{64}$ .

Then  $f_{X_1, X_2, X_3, X_4}(3, 7, 15, 25) = P(X_1 = 3, X_2 = 7, X_3 = 15, X_4 = 25)$

$$= \frac{50!}{3!7!15!25!} \left(\frac{1}{64}\right)^3 \left(\frac{7}{64}\right)^7 \left(\frac{19}{64}\right)^{15} \left(\frac{37}{64}\right)^{25}.$$

(b) By Theorem 10.2.2,  $X_3$  is a binomial random variable with parameters  $n (= 50)$  and

$$p_3 \left(= \frac{19}{64}\right). \text{ Therefore, } \text{Var}(X_3) = np_3(1 - p_3) = 50 \left(\frac{19}{64}\right) \left(\frac{45}{64}\right) = 10.44.$$

**10.2.8**  $M_{X_1, X_2, X_3}(t_1, t_2, t_3) = \sum \sum \sum e^{t_1 k_1 + t_2 k_2 + t_3 k_3} \cdot \frac{n!}{k_1! k_2! k_3!} \cdot p_1^{k_1} p_2^{k_2} p_3^{k_3} =$   
 $\sum \sum \sum \frac{n!}{k_1! k_2! k_3!} (p_1 e^{t_1})^{k_1} (p_2 e^{t_2})^{k_2} (p_3 e^{t_3})^{k_3}$ , where the summation extends over all the

values of  $(k_1, k_2, k_3)$  such that  $k_i \geq 0$ ,  $i = 1, 2, 3$  and  $k_1 + k_2 + k_3 = n$ . Recall Newton's binomial expansion. Applied here, it follows that the triple sum defining the moment-generating function for  $(X_1, X_2, X_3)$  can also be written  $(p_1 e^{t_1} + p_2 e^{t_2} + p_3 e^{t_3})^n$ .

**10.2.9** Assume that  $M_{X_1, X_2, X_3}(t_1, t_2, t_3) = (p_1 e^{t_1} + p_2 e^{t_2} + p_3 e^{t_3})^n$ .

Then  $M_{X_1, X_2, X_3}(t_1, 0, 0) = E(e^{t_1 X_1}) = (p_1 e^{t_1} + p_2 + p_3)^n = (1 - p_1 + p_1 e^{t_1})^n$  is the mgf for  $X_1$ .

But the latter has the form of the mgf for a binomial random variable with parameters  $n$  and  $p_1$ .

**10.2.10** The log of the likelihood vector  $(k_1, k_2, \dots, k_t)$  is  $\log L = \log p_1^{k_1} p_2^{k_2} \dots p_t^{k_t} = k_1 \log p_1 + k_2 \log p_2 + \dots + k_t \log p_t$ , where the  $p_i$ 's are constrained by the condition that  $\sum_{i=1}^t p_i = 1$ .

Finding the MLE for the  $p_i$ 's can be accomplished using Lagrange multipliers.

Differentiating  $\log L - \lambda \sum_{i=1}^t p_i$  with respect to each  $p_i$  gives  $\frac{\partial}{\partial p_i} \left[ \log L - \lambda \sum_{i=1}^t p_i \right] = \frac{k_i}{p_i} - \lambda$ ,

$i = 1, 2, \dots, t$ . But these derivatives equal 0 only if  $\frac{k_i}{p_i} = \lambda$  for all  $i$ . The latter equations,

together with the fact that  $\sum_{i=1}^t p_i = 1$ , imply that  $\hat{p}_i = \frac{k_i}{n}$ ,  $i = 1, 2, \dots, t$ .

## Section 10.3: Goodness-of-Fit Tests: All Parameters Known

$$10.3.1 \quad \sum_{i=1}^t \frac{(X_i - np_i)^2}{np_i} = \sum_{i=1}^t \frac{(X_i^2 - 2np_i X_i + n^2 p_i^2)}{np_i} = \sum_{i=1}^t \frac{X_i^2}{np_i} - 2 \sum_{i=1}^t X_i + n \sum_{i=1}^t p_i = \sum_{i=1}^t \frac{X_i^2}{np_i} - n.$$

$$10.3.2 \quad \text{If the hypergeometric model applies, } \pi_1 = P(0 \text{ whites are drawn}) = \frac{\binom{4}{0} \binom{6}{2}}{\binom{10}{2}} = \frac{15}{45},$$

$$\pi_2 = P(1 \text{ white is drawn}) = \frac{\binom{4}{1} \binom{6}{1}}{\binom{10}{2}} = \frac{24}{45}, \text{ and } \pi_3 = P(2 \text{ whites are drawn}) =$$

$$\frac{\binom{4}{2} \binom{6}{0}}{\binom{10}{2}} = \frac{6}{45}. \text{ Let } p_1, p_2, \text{ and } p_3 \text{ denote the actual probabilities of drawing 0, 1, and 2}$$

white chips, respectively. To test  $H_0: p_1 = \frac{15}{45}, p_2 = \frac{24}{45}, p_3 = \frac{6}{45}$  versus  $H_1: \text{at least one } p_i$

$\neq \pi_i$ , reject  $H_0$  if  $d \geq \chi_{1-\alpha, k-1}^2 = \chi_{.90, 2}^2 = 4.605$ .

$$\text{Here, } d = \frac{(35 - 100(15/45))^2}{100(15/45)} + \frac{(55 - 100(24/45))^2}{100(24/45)} + \frac{(10 - 100(6/45))^2}{100(6/45)} = 0.96, \text{ so } H_0$$

(and the hypergeometric model) would not be rejected.

10.3.3 If the sampling is presumed to be with replacement, the number of white chips selected would follow a binomial distribution. Specifically,  $\pi_1 = P(0 \text{ whites are drawn}) =$

$$\frac{\binom{2}{0} \left(\frac{4}{10}\right)^0 \left(\frac{6}{10}\right)^2}{\binom{2}{0} \left(\frac{4}{10}\right)^0 \left(\frac{6}{10}\right)^2} = 0.36, \pi_2 = P(1 \text{ white is drawn}) = \frac{\binom{2}{1} \left(\frac{4}{10}\right)^1 \left(\frac{6}{10}\right)^1}{\binom{2}{1} \left(\frac{4}{10}\right)^1 \left(\frac{6}{10}\right)^1} = 0.48, \text{ and } \pi_3 =$$

$$P(2 \text{ whites are drawn}) = \frac{\binom{2}{2} \left(\frac{4}{10}\right)^2 \left(\frac{6}{10}\right)^0}{\binom{2}{2} \left(\frac{4}{10}\right)^2 \left(\frac{6}{10}\right)^0} = 0.16. \text{ The form of the } \alpha = 0.10 \text{ decision rule is}$$

reject  $H_0$  if  $d \geq \chi_{1-\alpha, k-1}^2 = \chi_{.90, 2}^2 = 4.605$ .

$$\text{In this case, though, } d = \frac{(35 - 100(0.36))^2}{100(0.36)} + \frac{(55 - 100(0.48))^2}{100(0.48)} + \frac{(10 - 100(0.16))^2}{100(0.16)} = 3.30.$$

The null hypothesis that the sampling occurred with replacement is not rejected.

10.3.4 If births occur randomly in time, then  $\pi_1 = P(\text{baby is born between midnight and 4 A.M.}) =$

$\frac{1}{6}$  and  $\pi_2 = P(\text{baby is born at a "convenient" time}) = 1 - \pi_1 = \frac{5}{6}$ . Let  $p_1$  and  $p_2$  denote the actual probabilities of birth during those two time periods. The null hypothesis to be tested is

$H_0: p_1 = \frac{1}{6}, p_2 = \frac{5}{6}$ . At the  $\alpha = 0.05$  level of significance,  $H_0$  should be rejected if  $d \geq \chi_{.95, 1}^2 =$

3.841. Given that  $n = 2650$  and that  $X_1 = \text{number of births between midnight and 4 A.M.} =$

$$494, \text{ it follows that } d = \frac{(494 - 2650(1/6))^2}{2650(1/6)} + \frac{(2156 - 2650(5/6))^2}{2650(5/6)} = 7.44. \text{ Since the}$$

latter exceeds 3.841, we reject the hypothesis that births occur uniformly in all time periods.

**10.3.5** Let  $p = P(\text{baby is born between midnight and 4 A.M.})$ . Test  $H_0: p = \frac{1}{6}$  versus  $H_1: p \neq \frac{1}{6}$ .

Let  $n = 2650$  be the number of births and  $k = 494$  is the number of babies born between midnight and 4 A.M. From Theorem 6.3.1,  $H_0$  should be rejected if  $z$  is either  $\leq -1.96$  or

$\geq 1.96 = z_{.025}$ . Here  $z = \frac{494 - 2650(1/6)}{\sqrt{2650(1/6)(5/6)}} = 2.73$ , so  $H_0$  is rejected. These two test

procedures are equivalent: If one rejects  $H_0$ , so will the other. Notice that  $z_{.025}^2 = (1.96)^2 = 3.84 = \chi_{.95,1}^2$  and (except for a small rounding error)  $z^2 = (2.73)^2 = 7.45 = \chi^2 = 7.44$ .

**10.3.6** In the terminology of Theorem 10.3.1,  $X_1 = 1383$  = number of schizophrenics born in first quarter and  $X_2$  = number of schizophrenics born after the first quarter. By assumption,  $n\pi_1 = 1292.1$  and  $n\pi_2 = 3846.9$  (where  $n = 5139$ ). The null hypothesis that birth month is unrelated to schizophrenia is rejected if  $d \geq \chi_{.95,1}^2 = 3.841$ .

But  $d = \frac{(1383 - 1292.1)^2}{1292.1} + \frac{(3756 - 3846.9)^2}{3846.9} = 8.54$ , so  $H_0$  is rejected, suggesting that month of birth may, indeed, be a factor in the incidence of schizophrenia.

**10.3.7** Listed in the accompanying table are the observed and expected numbers of M&Ms of each color. Let  $p_1$  = true proportion of browns,  $p_2$  = true proportion of yellows, and so on.

Color	Observed Frequency	$p_i$	Expected Frequency
Brown	455	0.3	458.1
Yellow	343	0.2	305.4
Red	318	0.2	305.4
Orange	152	0.1	152.7
Blue	130	0.1	152.7
Green	<u>129</u>	0.1	<u>152.7</u>
	1527		1527

To test  $H_0: p_1 = 0.30, p_2 = 0.20, \dots, p_6 = 0.10$  versus  $H_1$ : at least one  $p_i \neq \pi_i$ , reject  $H_0$  if  $d \geq \chi_{.95,5}^2 = 11.070$ . But  $d = \frac{(455 - 458.1)^2}{458.1} + \dots + \frac{(129 - 152.7)^2}{152.7} = 12.23$ , so  $H_0$  is rejected (these particular observed frequencies are not consistent with the company's intended probabilities).

**10.3.8** The table below is from Question 3.2.16. It gives the information necessary for calculating the goodness-of-fit statistic  $d$ . The "Bernoulli model" is rejected if  $d \geq \chi_{.90,3}^2 = 6.251$ . For these data,  $d = \frac{(13 - 8)^2}{8} + \frac{(11 - 16)^2}{16} + \frac{(14 - 20)^2}{20} + \frac{(26 - 20)^2}{20} = 8.29$ , so  $H_0$  is rejected.

Number of Games	Observed Frequency	Expected Frequency
4	13	8
5	11	16
6	14	20
7	<u>26</u>	<u>20</u>
	64	64

**10.3.9** Let  $p_i = P(\text{horse starting in post position } i \text{ wins})$ ,  $i = 1, 2, \dots, 8$ . One relevant null hypothesis to test would be that  $p_i$  is not a function of  $i$ —that is,  $H_0: p_1 = p_2 = \dots = p_8 = \frac{1}{8}$  versus  $H_1$ : at least one  $p_i \neq \frac{1}{8}$ . If  $\alpha = 0.05$ ,  $H_0$  should be rejected if  $d \geq \chi_{.95,7}^2 = 14.067$ . Each  $E(X_i)$  in this case is  $144 \cdot \frac{1}{8} = 18.0$ , so  $d = \frac{(32-18.0)^2}{18.0} + \frac{(21-18.0)^2}{18.0} + \dots + \frac{(11-18.0)^2}{18.0} = 18.22$ . Since  $18.22 \geq \chi_{.95,7}^2 = 14.067$ , we reject  $H_0$  (which is not surprising because faster horses are often awarded starting positions close to the rail).

**10.3.10** We reject  $H_0$  if  $d \geq \chi_{.95,3-1}^2 = 5.991$ . The  $d$  statistic from the table below is

$$\frac{(23-23.25)^2}{23.25} + \frac{(50-46.50)^2}{46.50} + \frac{(20-23.25)^2}{23.25} = 0.72$$

Phenotype	Observed Frequency	Expected Frequency
Extreme frizzle	23	23.25
Mild frizzle	50	46.50
Normal	<u>20</u>	<u>23.25</u>
	93	93.00

The null hypothesis is not rejected.

**10.3.11** Let the random variable  $Y$  denote the prison time served by someone convicted of grand theft auto. In the accompanying table is the frequency distribution for a sample of 50  $y_i$ 's, together with expected frequencies based on the null hypothesis that  $f_Y(y) = \frac{1}{9}y^2$ ,  $0 \leq y \leq 3$ .

For example,  $E(X_1) = 50 \cdot \pi_1 = 50 \int_0^1 \frac{1}{9}y^2 dy = 1.85$ . Combining the first two intervals

(because  $E(X_1) < 5$ ) yields  $k = 2$  final classes, so  $H_0: f_Y(y) = \frac{1}{9}y^2$ ,  $0 \leq y \leq 3$  should be

rejected if  $d \geq \chi_{.95,1}^2 = 3.841$ . But  $d = \frac{(24-14.81)^2}{14.81} + \frac{(26-35.19)^2}{35.19} = 8.10$ , implying that the proposed quadratic pdf does not provide a good model for describing prison time.

Prison Time	Observed Frequency	$p_i$	Expected Frequency
$0 \leq y < 1$	8	1/27	1.85
$1 \leq y < 2$	16	7/27	12.96
$2 \leq y < 3$	<u>26</u>	19/27	<u>35.19</u>
	50		50.00

- 10.3.12** Listed is the frequency distribution for the 70  $y_i$ 's using classes of width 10 starting at 220. If normality holds, each  $\pi_i$  is an integral of the normal pdf having  $\mu = 266$  and  $\sigma = 16$ .

Duration	Observed Frequency	$\pi_i$	Expected Frequency
$220 \leq y < 230$	1	0.0122	0.854
$230 \leq y < 240$	5	0.0394	2.758
$240 \leq y < 250$	10	0.1071	7.497
$250 \leq y < 260$	16	0.1933	13.531
$260 \leq y < 270$	23	0.2467	17.269
$270 \leq y < 280$	7	0.2119	14.833
$280 \leq y < 290$	6	0.1226	8.582
$290 \leq y < 300$	<u>2</u>	0.0668	<u>4.676</u>
	70		70

For example,  $\pi_2 = P(230 \leq Y < 240) = P\left(\frac{230 - 266}{16} \leq \frac{Y - 266}{16} < \frac{240 - 266}{16}\right)$

$= P(-2.25 \leq Z < -1.63) = 0.0394$ . To account for all the area under  $f_Y(y)$ , the intervals defining the first and last classes need to be extended to  $-\infty$  and  $+\infty$ , respectively. That is,  $\pi_1 = P(-\infty < Y < 230)$  and  $\pi_8 = P(290 \leq Y < \infty)$ . Some of the expected frequencies ( $= 70 \cdot \pi_i$ ) are too small (i.e., less than 5) for the  $\chi^2$  approximation to be fully adequate. The first three classes need to be combined, giving  $0.854 + 2.758 + 7.497 = 11.109$ . Also, the last two class should be combined to yield  $8.582 + 4.676 = 13.258$ . With  $t = 5$  final classes, then, the normality assumption is rejected if  $d \geq \chi_{90,4}^2 = 7.779$ .

Here,  $d = \frac{(16 - 11.109)^2}{11.109} + \dots + \frac{(8 - 13.258)^2}{13.258} = 1.729$ . Do not reject the null hypothesis.

## Section 10.4: Goodness-of-Fit Tests: Parameters Unknown

- 10.4.1** Let  $p = P(\text{voter says "yes"})$ . Then  $\hat{p} = \frac{\text{number of yeses}}{\text{number of voters}} = \frac{30(0) + 56(1) + 73(2) + 41(3)}{600}$
- $= 0.54$ , so the  $H_0$  model to be tested is  $P(i \text{ yeses}) = \binom{3}{i} (0.54)^i (0.46)^{3-i}$ ,  $i = 0, 1, 2, 3$ . Detailed in the accompanying table are the relevant observed and expected frequencies.
- At the  $\alpha = 0.05$  level, the binomial model should be rejected if  $d_1 \geq \chi_{95,4-1-1}^2 = 5.991$ .

No. Saying "Yes"	Observed Frequency	$\hat{p}_i$	Expected Frequency
0	30	0.097	19.4
1	56	0.343	68.6
2	73	0.402	80.4
3	<u>41</u>	0.157	<u>31.4</u>
	200		200.0

But  $d_1 = \frac{(30-19.4)^2}{19.4} + \frac{(56-68.6)^2}{68.6} + \frac{(73-80.4)^2}{80.4} + \frac{(41-31.4)^2}{31.4} = 11.72$ , implying that the binomial model is inadequate in this particular context (probably because the trials are not likely to be independent, which is one of the model's assumptions).

- 10.4.2** For the Poisson pdf,  $\hat{\lambda} = \frac{59(0) + 27(1) + 9(2) + 1(3)}{96} = 0.50$  so the hypotheses being tested are  $H_0: P(i \text{ vacancies}) = e^{-0.50}(0.50)^i/i!, i = 0, 1, 2, \dots$  vs.  $H_1: P(i \text{ vacancies}) \neq e^{-0.50}(0.50)^i/i!, i = 0, 1, 2, \dots$  As the table indicates, the original frequency distribution needs to have the 2, 3, and 4+ classes combined because the expected frequencies are too small.

No. of Vacancies	Observed Frequency	$\hat{p}_i$	Expected Frequency
0	59	0.607	58.3
1	27	0.303	29.1
2	9	0.076	7.3
3	1	0.013	1.2
4+	0	0.001	0.1
	96		96.00

With the collapsed classes,  $d_1 = \frac{(59-58.3)^2}{58.3} + \frac{(27-29.1)^2}{29.1} + \frac{(10-8.6)^2}{8.6} = 0.39$ . For  $\alpha = 0.01$ ,  $H_0$  should be rejected if  $d_1 \geq \chi_{99,3-1}^2 = 6.635$ . The Poisson fit in this case is exceptionally good.

- 10.4.3** Here the  $H_0$  model is  $P(y \text{ infected plants}) = e^{-\hat{\lambda}}(\hat{\lambda})^i / i!, i = 0, 1, 2, \dots$ , where  $\hat{\lambda} = \frac{38(0) + 57(1) + \dots + 1(12)}{270} = 2.53$ . The classes from 6 to 13+ should be collapsed making the new last class 6+ with observed frequency 28 and expected frequency 11.9. As the table clearly shows, the Poisson model is inappropriate for these data. The disagreements between the observed and expected frequencies are considerable, and  $d_1 = \frac{(38-21.5)^2}{21.5} + \dots + \frac{(28-11.9)^2}{11.9} = 46.8$ , which greatly exceeds the  $\alpha = 0.05$  critical value,  $\chi_{95,7-1}^2 = 11.070$ . The independence assumption would not hold if the infestation was contagious (which is likely to be the case).

No. of Infected Plants	Observed Frequency	$\hat{p}_i$	Expected Frequency
0	38	0.0797	21.5
1	57	0.2015	54.4
2	68	0.2549	68.8
3	47	0.215	58.1
4	23	0.136	36.7
5	9	0.0688	18.6
6	10	0.0290	7.8
7	7	0.0105	2.8
8	3	0.0033	0.9
9	4	0.0009	0.2
10	2	0.0002	0.1

11	1	0.0001	0.0
12	1	0	0.0
13+	<u>0</u>	0	<u>0.0</u>
	270		270.0

**10.4.4** Let  $\hat{\lambda} = \frac{109(0) + 65(1) + 22(2) + 3(3) + 4(4)}{200} = 0.61$ . Then the model to be fit under  $H_0$  is the

Poisson pdf,  $p_X(i) = e^{-0.61}(0.61)^i/i!$ ,  $i = 0, 1, 2, \dots$ . Using  $t = 4$  final classes (the combined “4.8” is close enough to 5 for the  $\chi^2$  approximation to be adequate), we should reject  $H_0$  if  $d_1 \geq \chi_{99,4-1}^2 = 9.210$ . In the table, the observed and expected frequencies are in excellent agreement, so  $d_1$  will be very small (and the Poisson model will not be rejected).

$$\text{Specifically, } d_1 = \frac{(109 - 108.7)^2}{108.7} + \frac{(65 - 66.3)^2}{66.3} + \frac{(22 - 20.2)^2}{20.2} + \frac{(4 - 4.8)^2}{4.8} = 0.32.$$

No. of Deaths	Observed Frequency	$\hat{p}_i$	Expected Frequency
0	109	0.5434	108.7
1	65	0.3314	66.3
2	22	0.1011	20.2
3	3	0.0206	4.1
4+	<u>1</u>	0.0035	<u>0.7</u>
	200		200.0

**10.4.5** Under  $H_0$ , the intervals between shutdowns should be described by an exponential pdf,  $f_Y(y) = \hat{\lambda}e^{-\hat{\lambda}y}$ ,  $y > 0$  where  $\hat{\lambda} = 1/\bar{y}$  (recall Theorem 4.2.3). Here, the sample mean can be approximated by assigning each observation in a range a value equal to the midpoint of that range. Therefore,  $\bar{y} = \frac{130(0.5) + 41(1.5) + \dots + 1(7.5)}{211} = 1.22$ , which makes  $\hat{\lambda} = 0.82$ .

Moreover, each  $\hat{p}_i$  is an area under  $f_Y(y)$ . For example,  $\hat{p}_1 = \int_0^1 0.82e^{-0.82y} dy = 0.56$ . The complete set of  $\hat{p}_i$ 's and estimated expected frequencies are listed in the accompanying table. Using  $t = 5$  final classes, we should reject the exponential model if  $d_1 \geq \chi_{95,5-1}^2 = 7.815$ . But  $d_1 = \frac{(130 - 118.16)^2}{118.16} + \dots + \frac{(7 - 8.01)^2}{8.01} = 4.2$ , so  $H_0$  is not rejected.

Interval	Observed Frequency	$\hat{p}_i$	Expected Frequency
$0 \leq y < 1$	130	0.560	118.16
$1 \leq y < 2$	41	0.246	51.91
$2 \leq y < 3$	25	0.109	23.00
$3 \leq y < 4$	8	0.047	9.92
$4 \leq y < 5$	2	0.021	4.43
$5 \leq y < 6$	3	0.010	2.11
$6 \leq y < 7$	1	0.004	0.84
$y \geq 7$	<u>1</u>	0.003	<u>0.63</u>
	211		211.00

- 10.4.6** Below is the set of observed and expected frequencies, the latter based on the null hypothesis that the states' SAT scores are normally distributed with  $\bar{y} = 949.4$  and  $s = 68.4$ . With  $t = 4$  classes and two estimated parameters,  $H_0$  should be rejected if  $d_1 \geq \chi_{.95,4-2}^2 = 3.841$ . For these data,  $d_1 = \frac{(18-12.2)^2}{12.2} + \frac{(10-13.7)^2}{13.7} + \frac{(6-13.5)^2}{13.5} + \frac{(17-11.6)^2}{11.6} = 10.44$ , suggesting that the normality assumption is unwarranted.

Range	Observed Frequency	$\hat{p}_i$	Expected Frequency
$\leq 900$	18	0.2389	12.2
901–950	10	0.2691	13.7
950–1000	6	0.2654	13.5
$\geq 1001$	<u>17</u>	0.2266	<u>11.6</u>
	51		51.0

- 10.4.7** If  $p = P(\text{child is a boy})$ ,  $\hat{p} = \frac{\text{number of boys}}{\text{number of children}} = \frac{24(0) + 64(1) + 32(2)}{240} = 0.533$ , so the

hypotheses to be tested are  $H_0: P(i \text{ boys}) = \binom{2}{i} (0.533)^i (0.467)^{2-i}$ ,  $i = 0, 1, 2$ , versus

$H_1: P(i \text{ boys}) \neq \binom{2}{i} (0.533)^i (0.467)^{2-i}$ ,  $i = 0, 1, 2$ . Summarized in the table are the observed

and expected numbers of families with 0, 1, and 2 boys.

Given that  $t = \text{number of classes} = 3$  and that one parameter has been estimated,  $H_0$  should be rejected if  $d_1 \geq \chi_{.95,3-1}^2 = 3.841$ . But  $d_1 = \frac{(24-26.2)^2}{26.2} + \frac{(64-59.7)^2}{59.7} + \frac{(32-34.1)^2}{34.1} = 0.62$ , implying that the binomial model should not be rejected.

No. of Boys	Observed Frequency	$\hat{p}_i$	Expected Frequency
0	24	0.2181	26.2
1	64	0.4978	59.7
2	<u>32</u>	0.2841	<u>34.1</u>
	120		120.0

- 10.4.8** The table below gives the observed frequencies for 100 supposedly random choices from the  $[0, 1]$  interval, as well as the expected values of 10 for each category. With 10 classes and no parameters estimated,  $H_0$  should be rejected if  $d_1 \geq \chi_{.95,10-1}^2 = 16.919$ . For these data,

$$d_1 = \frac{(12-10)^2}{10} + \frac{(9-10)^2}{10} + \dots + \frac{(8-10)^2}{10} = 1.8$$

We can accept the null hypothesis that the data come from a uniform pdf over  $[0, 1]$ .

Interval	Observed Frequency	Expected frequency
.000–.099	12	10
.100–.199	9	10
.200–.299	11	10
.300–.399	8	10
.400–.499	11	10
.500–.599	10	10

.600–.699	11	10
.700–.799	9	10
.800–.899	11	10
.900–.999	<u>8</u>	<u>10</u>
	100	100

**10.4.9** Given that  $\hat{\lambda} = 3.87$ , the model to fit under  $H_0$  is  $p_X(i) = e^{-3.87}(3.87)^i/i!$ ,  $i = 0, 1, 2, \dots$ . Multiplying the latter probabilities by 2608 gives the complete set of estimated expected frequencies, as shown in the table. No classes need to be combined, so  $t = 12$  and one parameter has been estimated. Let  $\alpha = 0.05$ . Then  $H_0$  should be rejected if

$$d_1 \geq \chi_{95,12-1}^2 = 18.307. \text{ But } d_1 = \frac{(57-54.5)^2}{54.5} + \frac{(203-210.5)^2}{210.5} + \dots + \frac{(6-5.9)^2}{5.9} = 12.90,$$

implying that the Poisson model should not be rejected.

No. Detected	Observed Frequency	$\hat{p}_i$	Expected Frequency
0	57	0.0209	54.5
1	203	0.0807	210.5
2	383	0.1562	407.4
3	525	0.2015	525.5
4	532	0.1949	508.3
5	408	0.1509	393.6
6	273	0.0973	253.8
7	139	0.0538	140.3
8	45	0.0260	67.8
9	27	0.0112	29.2
10	10	0.0043	11.2
11+	<u>6</u>	0.0023	<u>5.9</u>
	2608		2608.0

**10.4.10** Take  $\hat{\lambda}$  to be the mean of the data or 1.818. The model to be fit, then, is the Poisson pdf with parameter 1.818. The table gives the observed frequencies, the estimated probabilities, and the estimated frequencies. Note that the last two classes should be collapsed, giving a total of six classes. With one parameter estimated, we should reject  $H_0$  if  $d_1 \geq \chi_{95,6-1}^2 = 9.488$ .

$$\text{The data gives } d_1 = \frac{(75-71.3)^2}{71.3} + \frac{(125-129.8)^2}{129.8} + \frac{(126-117.9)^2}{117.9} + \frac{(60-71.7)^2}{71.7} + \frac{(34-32.6)^2}{32.6} + \frac{(20-16.7)^2}{16.7} = 3.55 \text{ and we can accept the Poisson model for these data.}$$

Number of Turnovers	Observed Frequency	$\hat{p}_i$	Expected frequency
0	75	0.162	71.3
1	125	0.295	129.8
2	126	0.268	117.9
3	60	0.163	71.7
4	34	0.074	32.6
5+	<u>20</u>	0.038	<u>16.7</u>
	440		440.0

- 10.4.11** The MLE for  $p$  is the reciprocal of the sample mean. Here,  $\hat{p} = \frac{50}{4(1) + 13(2) + \dots + 1(9)} = 0.26$ , so the  $H_0$  model becomes  $p_X(i) = (1 - 0.26)^{i-1}(0.26)$ ,  $i = 1, 2, \dots$ . Combining the last five classes (see the accompanying table) makes  $t = 5$ . Let  $\alpha = 0.05$ . Then  $H_0$  should be rejected if  $d_1 \geq \chi_{.95, 5-1}^2 = 7.815$ . In this case,  $d_1 = \frac{(4-13.00)^2}{13.00} + \frac{(13-9.62)^2}{9.62} + \dots + \frac{(16-15.00)^2}{15.00} = 9.22$ , which suggests that the 50 observations did not come from a geometric pdf.

Outcome	Observed Frequency	$\hat{p}_i$	Expected Frequency
1	4	0.2600	13.00
2	13	0.1924	9.62
3	10	0.1424	7.12
4	7	0.1054	5.27
5	5	0.0780	3.90
6	4	0.0577	2.89
7	3	0.0427	2.14
8	3	0.0316	1.58
9+	<u>1</u>	0.0898	<u>4.49</u>
	50		50.00

- 10.4.12** If the lottery is fair, all of the  $\binom{n}{50}$  possible samples of size 50 are equally likely. Since  $1/\binom{n}{50}$  is largest when  $n$  is as small as possible, the MLE for  $n$  is  $y_{\max}$ —in this case, 115. It follows that the  $H_0$  probability associated with a given range of numbers—that is,  $\hat{p}_i$ —should equal the number of numbers in the interval divided by 115. The table shows a frequency distribution for the 50 numbers drawn, together with the corresponding estimated expected frequencies. Let  $\alpha = 0.05$ . Since  $t = 6$ , the equally-likely model should be rejected if  $d_1 \geq \chi_{.95, 6-1}^2 = 9.488$ . But  $d_1 = \frac{(8-8.25)^2}{8.25} + \frac{(6-8.70)^2}{8.70} + \dots + \frac{(11-6.95)^2}{6.95} = 3.79$ . At the  $\alpha = 0.05$  level, then, we should accept the presumption that the lottery was fair.

Number Drawn	Observed Frequency	$\hat{p}_i$	Expected Frequency
$1 \leq y \leq 19$	8	0.165	8.25
$20 \leq y \leq 39$	6	0.174	8.70
$40 \leq y \leq 59$	7	0.174	8.70
$60 \leq y \leq 79$	10	0.174	8.70
$80 \leq y \leq 99$	8	0.174	8.70
$100 \leq y \leq 115$	<u>11</u>	0.139	<u>6.95</u>
	50		50.00

- 10.4.13** The expected frequencies are calculated using Case Study 5.3.1. For example, let  $Y$  be the head breath. Then for the second class,

$$\hat{p}_2 = P(136 < Y \leq 139) = P\left(\frac{136-143.8}{6} < Y \leq \frac{139-143.8}{6}\right) = P(-1.3 < Y \leq -0.8)$$

$= 0.2119 - 0.0968 = 0.1151$ . The expected frequency rounded to one decimal place is  $84(0.1151) = 9.7$ . The complete set of  $\hat{p}_i$ 's and estimated expected frequencies are listed in the accompanying table. The degrees of freedom are  $7 - 1 - 2 = 4$ . We should reject the normal model if  $d_1 \geq \chi_{90,4}^2 = 7.779$ . But  $d_1 = \frac{(8-8.1)^2}{8.1} + \frac{(7-9.7)^2}{9.7} + \dots + \frac{(8-9.6)^2}{9.6} = 4.36$ , so  $H_0$  is not rejected.

Interval	Observed Frequency	$\hat{p}_i$	Expected Frequency
$y \leq 136$	8	0.0968	8.1
$136 < y \leq 139$	7	0.1151	9.7
$139 < y \leq 142$	21	0.1702	14.3
$142 < y \leq 145$	15	0.1972	16.6
$145 < y \leq 148$	15	0.1787	15.0
$148 < y \leq 151$	10	0.1269	10.7
$y > 151$	<u>8</u>	0.1151	<u>9.6</u>
	84		84.0

**10.4.14** Use the observed and expected frequencies as given in Table 5.2.4. Collapse the last three categories to obtain an observed frequency of 8 and an expected frequency of 7.8, as in the table below. With 6 classes and 2 parameters estimated, the degrees of freedom are  $6 - 2 - 1 = 3$ . Then  $H_0$  should be rejected if  $d_1 \geq \chi_{95,3}^2 = 7.815$ . For these data,  $d_1 =$

$$\frac{(10-7.7)^2}{7.7} + \frac{(20-21.4)^2}{21.4} + \frac{(23-28.4)^2}{28.4} + \dots + \frac{(8-7.8)^2}{7.8} = 2.80 = 3.14$$

We fail to reject the null hypothesis, so the negative binomial pdf fits the data well.

Number of Earthquakes	Observed Frequency	Expected Frequency
0–10	10	7.7
11–15	20	21.4
16–20	23	28.4
21–25	27	22.4
26–30	12	12.3
> 30	8	7.8

## Section 10.5: Contingency Tables

- 10.5.1** To test  $H_0$ : Diet and income are independent at the  $\alpha = 0.10$  level, reject  $H_0$  if  $d_2 \geq \chi^2_{.90, (2-1)(2-1)} = 2.706$ . Based on the expected frequencies predicted by  $H_0$  in the table,  $d_2 = 4.35$  so reject  $H_0$ .

	Yes	No	
Low	121 (108.9)	501 (513.2)	622
Middle upper	54 (66.2)	324 (311.9)	378
	175	825	1000

- 10.5.2** At the  $\alpha = .05$  level,  $H_0$ : Type of company and importance of work force are independent is rejected if  $d_2 \geq \chi^2_{.95, (2-1)(2-1)} = 3.841$ . But  $d_2 = \frac{(168 - 163.79)^2}{163.79} + \dots + \frac{(26 - 21.79)^2}{21.79} = 1.54$ , so  $H_0$  is not rejected.

	Manufacturing	Other	
Important	168 (163.79)	73 (77.21)	241
Not Important	42 (46.21)	26 (21.79)	68
	210	99	309

- 10.5.3** To test  $H_0$ : Delinquency and birth order are independent versus  $H_1$ : Delinquency and birth order are dependent at the  $\alpha = 0.01$  level, reject the null hypothesis if  $d_2 \geq \chi^2_{.99, (4-1)(2-1)} = 11.345$ . Here,  $d_2 = \frac{(24 - 45.59)^2}{45.59} + \dots + \frac{(70 - 84.05)^2}{84.05} = 42.25$ , suggesting that delinquency and birth order are related.

	Delinquent	Not Delinquent	
Oldest	24 (45.59)	450 (428.41)	474
In Between	29 (32.80)	312 (308.20)	341
Youngest	35 (23.66)	211 (222.34)	246
Only	23 (8.95)	70 (84.05)	93
	111	1043	1154

- 10.5.4** To test the null hypothesis that the outcome of the pregnancy and the time of the infection are independent, reject  $H_0$  if  $d_2 \geq \chi^2_{.99,(2-1)(2-1)} = 6.635$ . Looking at the contingency table, it appears that the risk of an abnormal birth increases dramatically when a rubella infection is contracted early in a pregnancy (compare the “observed” of 59 with the “expected” of 30.06). The value of the test statistic confirms that suspicion— $d_2 = \frac{(143 - 171.94)^2}{171.94} + \dots + \frac{(27 - 55.94)^2}{55.94} = 50.34$ , implying that  $H_0$  should be rejected.

	Early Infection	Late Infection	
Normal	143 (171.94)	349 (320.06)	492
Abnormal	59 (30.06)	27 (55.94)	86
	202	376	578

- 10.5.5** The null hypothesis that regular use of aspirin and breast cancer are independent should be rejected at the  $\alpha = 0.05$  level if  $d_2 \geq \chi^2_{.95,(2-1)(2-1)} = 3.841$ . These data suggest that the two are not independent (and  $H_0$  should be rejected)— $d_2 = \frac{(301 - 325.48)^2}{325.48} + \dots + \frac{(1075 - 1099.48)^2}{1099.48} = 4.79$

	Aspirin Use	Not Aspirin	
Breast Cancer	301 (325.48)	1141 (1116.52)	1442
Control Group	345 (320.52)	1075 (1099.48)	1420
	646	2216	2862

- 10.5.6** Let  $\alpha = 0.05$ . To test  $H_0$ : Children’s blood pressures are independent of their parent’s blood pressures versus  $H_1$ : Children’s blood pressures are not independent of their parent’s blood pressures, reject the null hypothesis if  $d_2 \geq \chi^2_{.95,(3-1)(3-1)} = 9.488$ . Here,  $d_2 = \frac{(14 - 11.12)^2}{11.12} + \dots + \frac{(12 - 8.83)^2}{8.83} = 3.81$ , so  $H_0$  would not be rejected. Based on these data, attempts to use one group to screen for high-risk individuals in the other group are not likely to be successful.

		Child’s Blood Pressure			
		Lower	Middle	Upper	
Father’s Blood Pressure	Lower	14 (11.12)	11 (11.48)	8 (10.40)	33
	Middle	11 (10.45)	11 (10.78)	9 (9.77)	31
	Upper	6 (9.43)	10 (9.74)	12 (8.83)	28
		31	32	29	92

**10.5.7** Given that  $\alpha = 0.05$ , the null hypothesis that early upbringing and aggressiveness later in life are independent is rejected if  $d_2 \geq \chi_{.95, (2-1)(2-1)}^2 = 3.841$ .

But  $d_2 = \frac{(27 - 40.25)^2}{40.25} + \dots + \frac{(93 - 106.25)^2}{106.25} = 12.61$ , so  $H_0$  is rejected—mice raised by foster mothers appear to be more aggressive than mice raised by their natural mothers.

	Natural Mother	Foster Mother	
No. Fighting	27 (40.25)	47 (33.75)	74
No. Not Fighting	140 (126.75)	93 (106.25)	233
	167	140	307

**10.5.8** The null hypothesis that grade distribution is independent of class section is rejected at the  $\alpha = 0.05$  level if  $d_2 \geq \chi_{.95, (3-1)(5-1)}^2 = 15.507$ .

For these data,  $d_2 = \frac{(11 - 12.4)^2}{12.4} + \dots + \frac{(11 - 12.8)^2}{12.8} = 18.49$ , so that there is statistical evidence that the section distributions are different.

	F	D	C	B	A	
801	11 (12.4)	19 (16.8)	18 (17.5)	20 (21.5)	13 (12.8)	81
842	12 (12.1)	21 (16.4)	16 (17.0)	16 (21.0)	14 (12.5)	79
845	14 (12.4)	10 (16.8)	18 (17.5)	28 (21.5)	11 (12.8)	81
	37	50	52	64	38	241

**10.5.9** Let  $\alpha = 0.05$ . To test the null hypothesis, we should reject  $H_0$  if  $d_2 \geq \chi_{.95, (4-1)(2-1)}^2 = 7.815$ .

Based on the table below, then  $d_2 = \frac{(34 - 25.5)^2}{25.5} + \dots + \frac{(17 - 13.3)^2}{13.3} = 9.13$ , so the appropriate conclusion would be that flying experience and the sex of children are not independent.

	Female	Male	
0–3	34 (25.5)	13 (21.5)	47
4–6	31 (34.1)	32 (28.9)	63
7–9	14 (15.7)	15 (13.3)	29
$\geq 10$	12 (15.7)	17 (13.3)	29
	91	77	168

**10.5.10** Let  $\alpha = 0.01$ . To test the null hypothesis, we should reject  $H_0$  if  $d_2 \geq \chi^2_{.99, (4-1)(4-1)} = 21.666$

Based on the table below, then  $d_2 = \frac{(115.9 - 94.9)^2}{94.9} + \dots + \frac{(16 - 16.8)^2}{16.8} = 22.64$ , so the

appropriate conclusion would be that grade distribution and year that calculus is taken are not independent.

	A	B	C	D-F	
1	115 (94.9)	91 (89.0)	65 (87.0)	42 (42.1)	313

3	107 (108.0)	85 (101.2)	121 (98.9)	43 (47.9)	356
4	37 (37.9)	35 (35.5)	37 (34.7)	16 (16.8)	125
	383	359	351	170	1263

# Chapter 11: Regression

## Section 11.2: The Method of Least Squares

$$11.2.1 \quad b = \frac{n \sum_{i=1}^n x_i y_i - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n y_i \right)}{n \left( \sum_{i=1}^n x_i^2 \right) - \left( \sum_{i=1}^n x_i \right)^2} = \frac{15(20,127.47) - (249.8)(1,200.6)}{15(4200.56) - (249.8)^2} = 3.291$$

$$a = \frac{\sum_{i=1}^n y_i - b \sum_{i=1}^n x_i}{n} = \frac{1,200.6 - 3.291(249.8)}{15} = 25.234$$

Then  $y = 25.234 + 3.291x$ ;  $y(18) = 84.5^\circ\text{F}$

$$11.2.2 \quad b = \frac{n \sum_{i=1}^n x_i y_i - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n y_i \right)}{n \left( \sum_{i=1}^n x_i^2 \right) - \left( \sum_{i=1}^n x_i \right)^2} = \frac{10(3973.35) - (36.5)(1070)}{10(204.25) - (36.5)^2} = 0.9953$$

$$a = \frac{\sum_{i=1}^n y_i - b \sum_{i=1}^n x_i}{n} = \frac{1070 - 0.9953(36.5)}{10} = 103.367$$

$$11.2.3 \quad b = \frac{n \sum_{i=1}^n x_i y_i - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n y_i \right)}{n \left( \sum_{i=1}^n x_i^2 \right) - \left( \sum_{i=1}^n x_i \right)^2} = \frac{9(24,628.6) - (234)(811.3)}{9(10,144) - (234)^2} = 0.8706$$

$$a = \frac{\sum_{i=1}^n y_i - b \sum_{i=1}^n x_i}{n} = \frac{811.3 - 0.8706(234)}{9} = 67.5088$$

As an example of calculating a residual, consider  $x_2 = 4$ . Then the corresponding residual is  $y_2 - \hat{y}_2 = 71.0 - [67.5088 + 0.8706(4)] = 0.0098$ . The complete set of residuals, rounded to two decimal places is

$x_i$	$y_i - \hat{y}_i$
0	-0.81
4	0.01
10	0.09
15	0.03
21	-0.09
29	0.14
36	0.55
51	1.69
68	-1.61

A straight line appears to fit these data.

**11.2.4** In the first graph, all of the residuals are positive. The residuals in the second graph alternate from positive to negative. Neither graph would normally occur from linear models.

**11.2.5** The value 12 is too “far” from the data observed.

**11.2.6** The problem here is the gap in  $x$  values, leaving some doubt as to the  $x$ - $y$  relationship.

**11.2.7** 
$$b = \frac{26(31,402) - (360)(2256.6)}{26(5365.08) - (360)^2} = 0.412$$

$$a = \frac{2256.6 - 0.412(360)}{26} = 81.088$$

The least squares line is  $81.088 + 0.412x$ . The plot of the data and least square line is:

- 11.2.8** (a) The sums needed are  $\sum_{i=1}^{13} x_i = 12.91$ ,  $\sum_{i=1}^{13} x_i^2 = 15.6171$ ,  $\sum_{i=1}^{13} y_i = 25.29$ ,  $\sum_{i=1}^{13} x_i y_i = 29.8762$

$$\text{Then } b = \frac{13(29.8762) - (12.91)(25.29)}{13(15.6171) - (12.91)^2} = 1.703; a = \frac{1}{13}(25.29) - \frac{1.703}{9}(12.91) = 0.255$$

The least squares line is  $y = 0.255 + 1.703x$ .

- (b) The residuals do not show a strong pattern, suggesting that a straight line fit is appropriate.

**11.2.9**

$$b = \frac{9(7,439.37) - (41.56)(1,416.1)}{9(289.4222) - (41.56)^2} = 9.23$$

$$a = \frac{(1,416.1) - 9.23(41.56)}{9} = 114.72$$

A linear relationship seems reasonable.

**11.2.10** The  $x$  values spread evenly across their range, and the scatter diagram has a linear trend. Fitting this data with a straight line seems appropriate.

**11.2.11** 
$$b = \frac{11(1141) - (111)(100)}{11(1277) - (111)^2} = 0.84$$

$$a = \frac{1072 - 0.84(111)}{11} = 0.61$$

The least squares line is  $y = 0.61 + 0.84x$ . The residuals given in the table below are large relative to the  $x$  values, which suggests that the linear fit is inadequate.

$x_i$	$y_i - \hat{y}_i$
7	-3.5
13	-1.5
14	-1.4
6	-0.7
14	2.6
15	1.8
4	3.0
8	2.7
7	-2.5
9	0.8
14	-1.4

**11.2.12** Using Cramer's rule we obtain

$$b = \frac{\begin{vmatrix} n & \sum_{i=1}^n y_i \\ \sum_{i=1}^n x_i & \sum_{i=1}^n x_i y_i \end{vmatrix}}{\begin{vmatrix} n & \sum_{i=1}^n x_i \\ \sum_{i=1}^n x_i & \sum_{i=1}^n x_i^2 \end{vmatrix}} = \frac{n \sum_{i=1}^n x_i y_i - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n y_i \right)}{n \left( \sum_{i=1}^n x_i^2 \right) - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n x_i \right)}$$

which is essentially the form of  $b$  in Theorem 11.2.1. The first row of the matrix equation is

$$na + \left( \sum_{i=1}^n x_i \right) b = \sum_{i=1}^n y_i.$$

Solving this equation for  $a$  in terms of  $b$  gives the expression in Theorem 11.2.1 for  $a$ .

**11.2.13** When  $\bar{x}$  is substituted for  $x$  in the least-squares line equation, we obtain  $y = a + b\bar{x} = \bar{y} - b\bar{x} + b\bar{x} = \bar{y}$

**11.2.14** The desired  $b$  is that value minimizing the equation  $L = \sum_{i=1}^n (y_i - bx_i)^2$ .

$$\frac{dL}{db} = \sum_{i=1}^n 2(y_i - bx_i)(-x_i), \text{ and setting } \frac{dL}{db} = 0 \text{ gives } \sum_{i=1}^n (x_i y_i - bx_i^2) = 0.$$

$$\text{The solution of this equation is } b = \frac{\sum_{i=1}^n x_i y_i}{\sum_{i=1}^n x_i^2}.$$

**11.2.15** For these data  $\sum_{i=1}^n d_i v_i = 95,161.2$ , and  $\sum_{i=1}^n d_i^2 = 2,685,141$ .

$$\text{Then } H = \frac{\sum_{i=1}^n d_i v_i}{\sum_{i=1}^n d_i^2} = \frac{95,161.2}{2,685,141} = 0.03544.$$

**11.2.16** (a) We seek the  $a$  value that minimizes the equation  $L = \sum_{i=1}^n (y_i - a - b^* x_i)^2$ .

$$\frac{dL}{da} = \sum_{i=1}^n 2(y_i - a - b^* x_i)(-1)$$

$$\text{Setting } \frac{dL}{da} = 0 \text{ gives } \sum_{i=1}^n (y_i - a - b^* x_i) = 0.$$

$$\text{The solution of this equation is } a = \frac{\sum_{i=1}^n y_i}{n} - b^* \frac{\sum_{i=1}^n x_i}{n} = \bar{y} - b^* \bar{x}$$

(b) We seek the  $b$  that minimizes the equation

$$L = \sum_{i=1}^n (y_i - a^* - bx_i)^2$$

$$\frac{dL}{db} = \sum_{i=1}^n 2(y_i - a^* - bx_i)(-x_i)$$

$$\text{Setting } \frac{dL}{db} = 0 \text{ gives } \sum_{i=1}^n (x_i y_i - a^* x_i - bx_i^2) = 0.$$

$$\text{The solution of this equation is } b = \frac{\sum_{i=1}^n x_i y_i - a^* \sum_{i=1}^n x_i}{\sum_{i=1}^n x_i^2}.$$

$$11.2.17 \quad b = \frac{\sum_{i=1}^n x_i y_i - a^* \sum_{i=1}^n x_i}{\sum_{i=1}^n x_i^2} = \frac{1513 - 100(45)}{575.5} = -5.19, \text{ so } y = 100 - 5.19x.$$

$$11.2.18 \quad (a) \text{ The sums needed are } \sum_{i=1}^{13} x_i^2 = 54,437, \sum_{i=1}^{13} x_i y_i = 3,329.4.$$

$$\text{Then } b = \frac{3329.4}{54,437} = 0.0612.$$

$$(b) y(120) = 0.612(\$120) = \$7.34 \text{ million}$$

$$11.2.19 \quad L = \sum_{i=1}^n (y_i - a - bx_i - c \sin x_i)^2. \text{ To find the } a, b, \text{ and } c, \text{ solve the following set of equations.}$$

$$(1) \frac{dL}{da} = \sum_{i=1}^n 2(y_i - a - bx_i - c \sin x_i)(-1) = 0 \text{ or } na + \left( \sum_{i=1}^n x_i \right) b + \left( \sum_{i=1}^n \sin x_i \right) c = \sum_{i=1}^n y_i$$

$$(2) \frac{dL}{db} = \sum_{i=1}^n 2(y_i - a - bx_i - c \sin x_i)(-x_i) = 0 \text{ or}$$

$$\left( \sum_{i=1}^n x_i \right) a + \left( \sum_{i=1}^n x_i^2 \right) b + \left( \sum_{i=1}^n x_i \sin x_i \right) c = \sum_{i=1}^n x_i y_i$$

$$(3) \frac{dL}{dc} = \sum_{i=1}^n 2(y_i - a - bx_i - c \sin x_i)(-\cos x_i) = 0 \text{ or}$$

$$\left( \sum_{i=1}^n \cos x_i \right) a + \left( \sum_{i=1}^n x_i \cos x_i \right) b + \left( \sum_{i=1}^n (\cos x_i)(\sin x_i) \right) c = \sum_{i=1}^n y_i \cos x_i$$

$$11.2.20 \quad (a) \text{ One choice for the model is } y = ae^{bx}. \text{ Then } \ln y \text{ is linear with } x. \text{ Using Theorem 11.2.1 on the pairs } (x_i, \ln y_i) \text{ gives}$$

$$b = \frac{n \sum_{i=1}^n x_i \ln y_i - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n \ln y_i \right)}{n \left( \sum_{i=1}^n x_i^2 \right) - \left( \sum_{i=1}^n x_i \right)^2} = \frac{10 \sum_{i=1}^n 137.97415 - (35)(41.35720)}{10(169) - 35^2} = -0.14572$$

$$\ln a = \frac{\sum_{i=1}^n \ln y_i - b \sum_{i=1}^n x_i}{n} = \frac{41.35720 - (-0.14572)(35)}{10} = 4.64574.$$

Then  $a$  rounded to three decimal places is  $e^{4.64574} = 104.140$ . The desired exponential fit is  $y = 104.140e^{-0.146x}$ . This model fits the data well. However, note that the initial percentage by this model is 104.141, when we know it must be 100. This discrepancy suggests using Question 11.2.16 where  $a^* = 100$ . In this case,

$$b = \frac{\sum_{i=1}^n x_i \ln y_i - \ln a^* \left( \sum_{i=1}^n x_i \right)}{\sum_{i=1}^n x_i^2} = \frac{137.97415 - 4.60517(35)}{169} = -0.13732.$$

This model is  $y = 100e^{-0.137x}$ .

- (b) For the first model, the half life is the solution to  $50 = 104.140e^{-0.146x}$ , or  $\ln(50/104.140) = -0.146x$ , so  $x = 5.025$ . For the second model, the half life is the solution to  $0.5 = e^{-0.137x}$  or  $\ln 0.5 = -0.137x$ , so  $x = 5.059$ .

- 11.2.21** (a) To fit the model  $y = ae^{bx}$ , note that  $\ln y$  is linear with  $x$ . Then

$$b = \frac{16(307.6276) - (120)(37.0457)}{16(1240) - 120^2} = 0.0876$$

$$\ln a = \frac{37.0457 - (0.0876)(120)}{16} = 1.6583$$

Then  $a = e^{1.6583} = 5.2506$ , and the model is  $y = 5.2506e^{0.0484x}$ .

- (b)

$y$	$\hat{y}$
2009	0.3253
2010	0.9209
2011	1.0016
2012	1.0286
2013	0.3213
2014	-0.1050
2015	-1.4176

The exponential model predicts more growth than actually occurred.

- 11.2.22** (a)  $b = \frac{10(491.332) - (55)(90.862)}{10(385) - 55^2} = -0.1019$

$$\ln a = \frac{90.862 - (-0.1019)(55)}{10} = 9.9467$$

Then  $a = e^{9.9467} = 15470.6506$ , and the model is  $y = 15470.6506e^{-0.1019x}$ .

(b)  $y = 15470 \cdot 6506e^{-0.1019(11)} = \$5043$

(c) The exponential curve, which fits the data very well, predicts that a car 0 years old will have a value of \$15471, but the selling price is \$16,200. The difference \$16,200 - \$15471 = \$729 could be considered initial depreciation.

11.2.23 
$$b = \frac{12(1453.58352) - (264)(54.92066)}{12(8096) - 264^2} = 0.107$$

$$\ln a = \frac{54.92066 - (0.107)(264)}{12} = 2.223$$

Then  $a = e^{2.218} = 9.235$ , and the model is  $y = 9.235e^{0.107x}$ .

11.2.24 (a) If  $\frac{dy}{dx} = by$ , then  $\frac{1}{y} \frac{dy}{dx} = b$ . Integrate both sides of the latter equality with respect to  $x$ :

$$\int \frac{1}{y} \frac{dy}{dx} dx = \int b dx, \text{ which implies that } \ln y = bx + C.$$

Now apply the function  $e^x$  to both sides to get  $y = e^{\beta_1 x} e^c = a e^{\beta_1 x}$ , where  $a = e^c$ .

(b)  $x$  on the abscissa,  $\ln y$  on the ordinate

11.2.25 
$$b = \frac{7(0.923141) - (-0.067772)(7.195129)}{7(0.0948679) - (-0.067772)^2} = 10.538;$$

$$\log a = \frac{1}{7}(7.195129) - \frac{10.538}{7}(-0.067772) = 1.1299$$

Then  $a = 10^{1.1299} = 13.487$ . The model is  $13.487x^{10.538}$ .

The table below gives a comparison of the model values and the observed  $y_i$ 's.

$x_i$	$y_i$	Model
0.98	25.000	10.901
0.74	0.950	0.565
1.12	200.000	44.522
1.34	150.000	294.677
0.87	0.940	3.109
0.65	0.090	0.144
1.39	260.000	433.516

$$11.2.26 \quad b = \frac{n \sum_{i=1}^n \log x_i \cdot \log y_i - \left( \sum_{i=1}^n \log x_i \right) \left( \sum_{i=1}^n \log y_i \right)}{n \left( \sum_{i=1}^n \log^2 x_i \right) - \left( \sum_{i=1}^n \log x_i \right)^2} = \frac{11(30.43743) - (17.74744)(18.01965)}{11(31.06763) - (17.74744)^2} = 0.56$$

$$\log a = \frac{\sum_{i=1}^n \log y_i - b \left( \sum_{i=1}^n \log x_i \right)}{n} = \frac{18.01965 - (0.56)(17.74744)}{11} = 0.73364$$

$$a = 10^{0.73364} = 5.42, \text{ and the model is } y = 5.42x^{0.56}$$

$$11.2.27 \quad b = \frac{4(36.95941) - (11.55733)(12.08699)}{4(34.80999) - 11.55733^2} = 1.43687$$

$$\log a = \frac{12.08699 - 1.43687(11.55733)}{4} = -1.12985$$

$$a = 10^{-1.12985} = 0.07416. \text{ The model is } y = 0.07416x^{1.43687}$$

$$11.2.28 \quad b = \frac{n \sum_{i=1}^n (1/x_i) y_i - \left( \sum_{i=1}^n 1/x_i \right) \left( \sum_{i=1}^n y_i \right)}{n \left( \sum_{i=1}^n (1/x_i)^2 \right) - \left( \sum_{i=1}^n 1/x_i \right)^2} = \frac{7(435.625) - (8.01667)(169.1)}{7(21.35028) - 8.01667^2} = 19.82681$$

$$a = \frac{\sum_{i=1}^n y_i - b \left( \sum_{i=1}^n 1/x_i \right)}{n} = \frac{169.7 - 19.82681(8.01667)}{7} = 1.53643$$

One quarter mile =  $0.25(5,280) = 1,320$  feet.

$y(1.32) = 1.53643 + (19.82681)(1/1.32) = 16.557$ , or \$16,557

$$11.2.29 \quad (d) \text{ If } y = \frac{1}{a + bx}, \text{ then } \frac{1}{y} = a + bx \text{ and } 1/y \text{ is linear with } x.$$

$$(e) \text{ If } y = \frac{x}{a + bx}, \text{ then } \frac{1}{y} = \frac{a + bx}{x} = b + a \frac{1}{x}, \text{ and } 1/y \text{ is linear with } 1/x.$$

$$(f) \text{ If } y = 1 - e^{-x^b/a}, \text{ then } 1 - y = e^{-x^b/a}, \text{ and } \frac{1}{1 - y} = e^{x^b/a}. \text{ Taking } \ln \text{ of both sides gives}$$

$$\ln \frac{1}{1 - y} = x^b / a. \text{ Taking } \ln \text{ again yields } \ln \ln \frac{1}{1 - y} = -\ln a + b \ln x, \text{ and } \ln \ln \frac{1}{1 - y} \text{ is linear with } \ln x.$$

$$11.2.30 \quad \text{Let } y' = \ln \left( \frac{700 - y}{y} \right). \text{ We find the linear relationship between } x \text{ and } y'. \text{ The needed sums}$$

$$\text{are } \sum_{i=1}^{10} x_i = 153, \sum_{i=1}^{10} x_i^2 = 1785, \sum_{i=1}^{10} y'_i = 1.75603, \sum_{i=1}^{10} x_i y'_i = -197.40071$$

$$b = \frac{18(-197.40071) - (153)(1.75603)}{18(1785) - (153)^2} = -0.4382$$

$$a = \frac{1.75603 - (-0.4382)(153)}{18} = 3.822$$

$$\text{The logistic curve has equation } y = \frac{700}{1 + e^{3.822 - 0.4382x}}$$

$$11.2.31 \quad \text{Let } y' = \ln \left( \frac{60 - y}{y} \right). \text{ We find the linear relationship between } x \text{ and } y'. \text{ The needed sums are}$$

$$\sum_{i=1}^8 x_i = 352, \sum_{i=1}^8 x_i^2 = 16160, \sum_{i=1}^8 y'_i = -2.39572, \sum_{i=1}^8 x_i y'_i = -194.88216.$$

$$b = \frac{8(-194.88216) - 352(-2.39572)}{8(16160) - 352^2} = -0.13314$$

$$a = \frac{-2.39572 - (-0.13314)(352)}{8} = 5.55870$$

## Section 11.3: The Linear Model

$$11.3.1 \quad \beta_1 = \frac{4(93) - 10(40.2)}{4(30) - 10^2} = -1.5$$

$$\beta_0 = \frac{(40.2) - (-1.5)(10)}{4} = 13.8$$

$$\text{Thus, } y = 13.8 - 1.5x. \quad t = \frac{\hat{\beta}_1 - \beta_1^0}{s / \sqrt{\sum_{i=1}^4 (x_i - \bar{x})^2}} = \frac{-1.5 - 0}{2.114 / \sqrt{5}} = -1.59.$$

Since  $-t_{0.025,2} = -4.3027 < t = -1.59 < 4.3027 = t_{0.025,2}$ , accept  $H_0$ .

$$11.3.2 \quad \begin{aligned} \text{(a) The radius of the confidence interval} &= t_{0.025,24} \frac{s}{\sqrt{\sum_{i=1}^{26} (x_i - \bar{x})^2}} = 2.0639 \frac{11.788481}{\sqrt{380.464615}} \\ &= 1.247 \end{aligned}$$

The center is  $\beta_1 = 0.412$ , and the confidence interval is  $(-0.835, 1.659)$

(b) Since 0 is in the confidence interval, we cannot reject  $H_0$  at the 0.05 level of significance.

(c) See the solution to Question 11.2.7. The linear fit for  $11 \leq x \leq 14$  is not very good, suggesting a search for other contributing variables in that  $x$  range.

$$11.3.3 \quad t = \frac{\beta_1 - \beta_1^0}{s / \sqrt{\sum_{i=1}^{15} (x_i - \bar{x})^2}} = \frac{3.291 - 0}{3.829 / \sqrt{40.55733}} = 5.47.$$

Since  $t = 5.47 > t_{0.005,13} = 3.0123$ , reject  $H_0$ .

**11.3.4** To minimize the width of the interval, we must maximize  $\sum_{i=1}^n (x_i - \bar{x})^2$ . To accomplish this, take half of the  $x_i$  to be 0 and half to be +5.

**11.3.5**  $\text{Var}(\hat{\beta}_1) = \sigma^2 / \sum_{i=1}^9 (x_i - \bar{x})^2 = 45/60 = 0.75$ . The standard deviation of  $\hat{\beta}_1 = \sqrt{0.75} = 0.866$ .

$P(|\hat{\beta}_1 - \beta_1| < 1.5) = P\left(\frac{|\hat{\beta}_1 - \beta_1|}{0.866} < \frac{1.5}{0.866}\right) = P(|Z| < 1.73)$  for the standard normal random variable  $Z$ .  $P(Z > 1.73) = 1 - 0.9582 = 0.0418$ , so  $P(|Z| < 1.73) = 1 - 2(0.0418) = 0.9164$

$$\begin{aligned}
 \text{11.3.6} \quad \sum_{i=1}^n (Y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i)^2 &= \sum_{i=1}^n [Y_i - (\bar{Y} - \hat{\beta}_1 \bar{x}) - \hat{\beta}_1 x_i]^2 = \sum_{i=1}^n [(Y_i - \bar{Y}) - \hat{\beta}_1 (x_i - \bar{x})]^2 \\
 &= \sum_{i=1}^n (Y_i - \bar{Y})^2 + \hat{\beta}_1^2 \sum_{i=1}^n (x_i - \bar{x})^2 - 2\hat{\beta}_1 \sum_{i=1}^n (x_i - \bar{x})(Y_i - \bar{Y}) \\
 &= \sum_{i=1}^n (Y_i - \bar{Y})^2 + \hat{\beta}_1 \frac{\sum_{i=1}^n (x_i - \bar{x})(Y_i - \bar{Y})}{\sum_{i=1}^n (x_i - \bar{x})^2} \sum_{i=1}^n (x_i - \bar{x})^2 - 2\hat{\beta}_1 \sum_{i=1}^n (x_i - \bar{x})(Y_i - \bar{Y}) \\
 &= \sum_{i=1}^n (Y_i - \bar{Y})^2 - \hat{\beta}_1 \sum_{i=1}^n (x_i - \bar{x})(Y_i - \bar{Y}) = \sum_{i=1}^n Y_i^2 - n\bar{Y}^2 - \hat{\beta}_1 \left[ \sum_{i=1}^n x_i Y_i - \frac{1}{n} \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n Y_i \right) \right] \\
 &= \sum_{i=1}^n Y_i^2 - \hat{\beta}_1 \sum_{i=1}^n x_i Y_i - n\bar{Y}^2 + \frac{1}{n} \hat{\beta}_1 \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n Y_i \right) = \sum_{i=1}^n Y_i^2 - \hat{\beta}_1 \sum_{i=1}^n x_i Y_i - (\bar{Y} - \hat{\beta}_1 \bar{x}) \left( \sum_{i=1}^n Y_i \right) \\
 &= \sum_{i=1}^n Y_i^2 - \hat{\beta}_1 \sum_{i=1}^n x_i Y_i - \hat{\beta}_0 \sum_{i=1}^n Y_i
 \end{aligned}$$

**11.3.7** The radius of the confidence interval is

$$t_{.05,7} \frac{s \sqrt{\sum_{i=1}^n x_i^2}}{\sqrt{9} \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} = 1.8946 \frac{(0.959)\sqrt{10144}}{\sqrt{9}\sqrt{4060}} = 0.957.$$

The center of the interval is  $\hat{\beta}_0 = 67.508$ . The interval = (66.551, 68.465).

**11.3.8** Since there is no reason to believe that radioactivity decreases cancer rates, the test should be  $H_0: \beta_1 = 0$  versus  $H_1: \beta > 0$ .

$$t = \frac{\hat{\beta}_1 - \beta_1^0}{s / \sqrt{\sum_{i=1}^9 (x_i - \bar{x})^2}} = \frac{9.23 - 0}{14.010 / \sqrt{97.508}} = 6.51. \text{ Since } t = 6.51 > t_{.05,7} = 1.8946, \text{ reject } H_0.$$

$$\text{11.3.9} \quad t = \frac{\hat{\beta}_1 - \beta_1^0}{s / \sqrt{\sum_{i=1}^{11} (x_i - \bar{x})^2}} = \frac{0.84 - 0}{2.404 / \sqrt{156.909}} = 4.38. \text{ Since } t = 4.38 > t_{.025,9} = 2.2622, \text{ reject } H_0.$$

$$11.3.10 \quad E(\bar{Y}) = \frac{1}{n} \sum_{i=1}^n E(Y_i | x_i) = \frac{1}{n} \sum_{i=1}^n (\beta_0 + \beta_1 x_i) = \frac{1}{n} n \beta_0 + \beta_1 \frac{1}{n} \sum_{i=1}^n x_i = \beta_0 + \beta_1 \bar{x}$$

$$11.3.11 \quad \text{By Theorem 11.3.2, } E(\hat{\beta}_0) = \beta_0, \text{ and } \text{Var}(\hat{\beta}_0) = \frac{\sigma^2 \sum_{i=1}^n x_i}{n \sum_{i=1}^n (x_i - \bar{x})^2}.$$

Now,  $(\hat{\beta}_0 - \beta_0) / \sqrt{\text{Var}(\hat{\beta}_0)}$  is normal, so  $P\left(-z_{\alpha/2} < (\hat{\beta}_0 - \beta_0) / \sqrt{\text{Var}(\hat{\beta}_0)} < z_{\alpha/2}\right) = 1 - \alpha$ .

Then the confidence interval is  $(\hat{\beta}_0 - z_{\alpha/2} \sqrt{\text{Var}(\hat{\beta}_0)}, \hat{\beta}_0 + z_{\alpha/2} \sqrt{\text{Var}(\hat{\beta}_0)})$ , or

$$\left( \hat{\beta}_0 - z_{\alpha/2} \frac{\sigma \sqrt{\sum_{i=1}^n x_i}}{\sqrt{n} \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}}, \hat{\beta}_0 + z_{\alpha/2} \frac{\sigma \sqrt{\sum_{i=1}^n x_i}}{\sqrt{n} \sqrt{\sum_{i=1}^n (x_i - \bar{x})^2}} \right)$$

11.3.12 Refer to the four assumptions in the subsection “A Special Case”.

- (1) Normality of the data cannot be assessed from the scatter plot
- (2) The standard deviation does not appear to be the same for the three data sets.
- (3) The means could be collinear
- (4) Independence of the underlying random variables cannot be assessed from the scatter plot.

11.3.13 Reject the null hypothesis if the statistic is  $< \chi_{\alpha/2, n-2}^2 = \chi_{.025, 22}^2 = 10.982$  or  $> \chi_{1-\alpha/2, n-2}^2 = \chi_{.975, 22}^2 = 36.781$ . The observed chi square is  $\frac{(n-2)s^2}{\sigma_0^2} = \frac{(24-2)(18.2)}{12.6} = 31.778$ , so do not reject  $H_0$ .

11.3.14 Case Study 11.3.1 provides the value of  $s^2 = 2181.66$ . Then the confidence interval for  $\sigma^2$  is  $\left( \frac{(n-2)s^2}{\chi_{1-\alpha/2, n-2}^2}, \frac{(n-2)s^2}{\chi_{\alpha/2, n-2}^2} \right) = \left( \frac{(19)(2181.66)}{\chi_{.95, 19}^2}, \frac{(19)(2181.66)}{\chi_{.05, 19}^2} \right) = \left( \frac{41,451.54}{30.144}, \frac{41,451.54}{10.177} \right) = (1375.12, 4097.22)$

11.3.15 The value of  $t$  is given to be 2.31, so  $s^2 = 5.3361$ . Then the confidence interval for  $\sigma^2$  is  $\left( \frac{(n-2)s^2}{\chi_{1-\alpha/2, n-2}^2}, \frac{(n-2)s^2}{\chi_{\alpha/2, n-2}^2} \right) = \left( \frac{(6)(5.3361)}{\chi_{.95, 7}^2}, \frac{(6)(5.3361)}{\chi_{.05, 7}^2} \right) = \left( \frac{32.0166}{14.067}, \frac{32.0166}{2.167} \right) = (2.276, 14.775)$

11.3.16 (a) The radius of the confidence interval is

$$t_{.25, 16} s \sqrt{\frac{1}{n} + \frac{(x - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2}} = 2.1199(0.202) \sqrt{\frac{1}{18} + \frac{(14.0 - 15.0)^2}{96.38944}} = 0.110$$

The center is  $\hat{y} = \hat{\beta}_0 + \hat{\beta}_1 x = -0.104 + 0.988(14.0) = 13.728$ .

The confidence interval is (13.62, 13.84).

(b) The radius of the prediction interval is

$$t_{.025,16} s \sqrt{1 + \frac{1}{n} + \frac{(x - \bar{x})^2}{\sum_{i=1}^{18} (x_i - \bar{x})^2}} = 2.1199(0.202) \sqrt{1 + \frac{1}{18} + \frac{(14.0 - 15.0)^2}{96.38944}} = 0.442$$

The center is  $\hat{y} = \hat{\beta}_0 + \hat{\beta}_1 x = -0.104 + 0.988(14.0) = 13.728$ . The confidence interval is (13.29, 14.17).

**11.3.17** The radius of the 95% confidence interval is

$$2.0687(0.0113) \sqrt{\frac{1}{25} + \frac{(2.750 - 2.643)^2}{0.0367}} = 0.0139.$$

The center is  $\hat{y} = \hat{\beta}_0 + \hat{\beta}_1 x = 0.308 + 0.642(2.750) = 2.0735$ . The confidence interval is (2.0596, 2.0874).

**11.3.18** The radius of the 99% confidence interval is

$$2.8609(46.708) \sqrt{\frac{1}{21} + \frac{(2500 - 2148.095)^2}{13056523.81}} = 31.932.$$

The center is  $\hat{y} = \hat{\beta}_0 + \hat{\beta}_1 x = 15.771 + 0.060(2500) = 165.771$ . The confidence interval is (133.839, 197.703). If the official were interested in a specific country, the prediction interval would be of more use.

**11.3.19** The radius of the 95% confidence interval for  $E(Y | 2890)$  is  $t_{.025,10} s \sqrt{\frac{1}{n} + \frac{(x - \bar{x})^2}{\sum_{i=1}^{18} (x_i - \bar{x})^2}}$

$$= 2.2281(1.2849) \sqrt{\frac{1}{12} + \frac{(2890 - 2961.667)^2}{2,346,716.667}} = 0.8372.$$

The center is  $\hat{y} = \hat{\beta}_0 + \hat{\beta}_1 x = 56.2653 - 0.0096(2890) = 28.5213$ . The 95% confidence interval is  $(28.5123 - 0.8372, 28.5123 + 0.8372) = (27.6751, 29.3585)$ .

The Honda Civic mileage of 37 does not lie in the interval, but it is a different type of automobile than those in the data set.

**11.3.20** The radius of the 95% confidence interval for is  $2.3646(14.010) \sqrt{\frac{1}{9} + \frac{(9 - 4.618)^2}{97.507}} = 18.387$ .

The center is  $\hat{y} = \hat{\beta}_0 + \hat{\beta}_1 x = 114.72 + 9.23(9) = 197.79$ . The confidence interval is  $(197.79 - 18.387, 197.79 + 18.387) = (179.40, 216.18)$ .

The radius of the 95% prediction interval is  $2.3646(14.010) \sqrt{\frac{1}{9} + \frac{(9 - 4.618)^2}{97.507}} = 37.888$ .

The prediction interval is  $(197.79 - 37.888, 197.79 + 37.888) = (159.90, 235.68)$

**11.3.21** The test statistic is  $t = \frac{\hat{\beta}_1 - \hat{\beta}_1^*}{s \sqrt{\frac{1}{\sum_{i=1}^6 (x_i - \bar{x})^2} + \frac{1}{\sum_{i=1}^8 (x_i^* - \bar{x}^*)^2}}}$ , where  $s = \sqrt{\frac{5.983 + 13.804}{6 + 8 - 4}} = 1.407$ .

Then  $t = 2.3646(14.010)\sqrt{\frac{1}{9} + \frac{(9 - 4.618)^2}{97.507}} = -1.42$ . Since the observed ratio is not less than

$-t_{.05,10} = -1.8125$  the difference in slopes can be ascribed to chance. These data do not support further investigation.

$$11.3.22 \quad s = \sqrt{\frac{1}{3+4}(3s^2 + 4s^{*2})} = \sqrt{\frac{1}{7}[3(0.9058^2) + 4(1.2368^2)]} = 1.1071.$$

Then  $t = \frac{-3.4615 + 2.7373}{1.1071\sqrt{\frac{1}{26} + \frac{1}{39.3333}}} = -2.59$ . Since  $t = -2.59 < -t_{.025,7} = -2.3646$ , reject  $H_0$ .

$$11.3.23 \quad \text{The form given in the text is } \text{Var}(\hat{Y}) = \sigma^2 \left[ \frac{1}{n} + \frac{(x - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2} \right].$$

Putting the sum in the brackets over a least common denominator gives

$$\begin{aligned} \frac{1}{n} + \frac{(x - \bar{x})^2}{\sum_{i=1}^n (x_i - \bar{x})^2} &= \frac{\sum_{i=1}^n (x_i - \bar{x})^2 + n(x - \bar{x})^2}{n \sum_{i=1}^n (x_i - \bar{x})^2} = \frac{\sum_{i=1}^n x_i^2 - n\bar{x}^2 + n(x^2 + \bar{x}^2 - 2x\bar{x})}{n \sum_{i=1}^n (x_i - \bar{x})^2} \\ &= \frac{\sum_{i=1}^n x_i^2 + nx^2 - 2nx\bar{x}}{n \sum_{i=1}^n (x_i - \bar{x})^2} = \frac{\sum_{i=1}^n x_i^2 + nx^2 - 2x \sum_{i=1}^n x_i}{n \sum_{i=1}^n (x_i - \bar{x})^2} = \frac{\sum_{i=1}^n (x_i - x)^2}{n \sum_{i=1}^n (x_i - \bar{x})^2}. \end{aligned}$$

$$\text{Thus } \text{Var}(\hat{Y}) = \frac{\sigma^2 \sum_{i=1}^n (x_i - x)^2}{n \sum_{i=1}^n (x_i - \bar{x})^2}.$$

$$11.3.24 \quad \begin{aligned} \sum_{i=1}^n (\hat{Y}_i - \bar{Y})^2 &= \sum_{i=1}^n (\hat{\beta}_0 + \hat{\beta}_1 x_i - \bar{Y})^2 = \\ \sum_{i=1}^n (\bar{Y} - \hat{\beta}_1 \bar{x} + \hat{\beta}_1 x_i - \bar{Y})^2 &= \sum_{i=1}^n (\hat{\beta}_1 x_i - \hat{\beta}_1 \bar{x})^2 = \hat{\beta}_1^2 \sum_{i=1}^n (x_i - \bar{x})^2. \end{aligned}$$

An application of Equation 11.3.2 completes the proof.

## Section 11.4: Covariance and Correlation

$$11.4.1 \quad E(XY) = 1 \frac{1+2(1)}{22} + 2 \frac{2+2(1)}{22} + 3 \frac{1+2(3)}{22} + 6 \frac{2+2(3)}{22} = 80/22 = 40/11$$

$$E(X) = 1 \frac{10}{22} + 2 \frac{12}{22} = 34/22 = 17/11$$

$$E(X^2) = 1 \frac{10}{22} + 4 \frac{12}{22} = 58/22 = 29/11$$

$$E(Y) = 1 \frac{7}{22} + 3 \frac{15}{22} = 52/22 = 26/11$$

$$E(Y^2) = 1 \frac{7}{22} + 9 \frac{15}{22} = 142/22 = 71/11$$

$$\text{Cov}(XY) = 40/11 - (17/11)(26/11) = -2/121$$

$$\text{Var}(X) = 29/11 - (17/11)^2 = 30/121$$

$$\text{Var}(Y) = 71/11 - (26/11)^2 = 105/121$$

$$\rho(X,Y) = \frac{-2/121}{\sqrt{30/121}\sqrt{105/121}} = \frac{-2}{\sqrt{3150}} = \frac{-2}{15\sqrt{14}} = 0.036$$

$$11.4.2 \quad E(XY) = \int_0^1 \int_0^1 xy(x+y) dy dx = \int_0^1 \left( \frac{x^2}{2} + \frac{x}{3} \right) dx = \frac{x^3}{6} + \frac{x^2}{6} \Big|_0^1 = 1/3.$$

$$f_X(x) = x + \frac{1}{2}, \text{ so } E(X) = \int_0^1 x \left( x + \frac{1}{2} \right) dx = 7/12$$

$$E(X^2) = \int_0^1 x^2 \left( x + \frac{1}{2} \right) dx = 5/12. \quad \text{Var}(X) = 5/12 - (7/12)^2 = 11/144.$$

By symmetry  $Y$  has the same moments, so  $\text{Cov}(X, Y) = 1/3 - (7/12)(7/12) = -1/144$ .

Then  $\rho = -1/11$ .

$$11.4.3 \quad f_X(x) = \int_0^x 8xy \, dy = 4x^3. \quad E(X) = \int_0^1 x(4x^3) dx = 4/5. \quad E(X^2) = \int_0^1 x^2(4x^3) dx = 2/3.$$

$$\text{Var}(X) = 2/3 - (4/5)^2 = 2/75$$

$$f_Y(y) = \int_y^1 8xy \, dx = 4(y - y^3). \quad E(Y) = 4 \int_0^1 (y - y^4) dy = 8/15. \quad E(Y^2) = 4 \int_0^1 (y^3 - y^5) dy = 1/3.$$

$$\text{Var}(Y) = 1/3 - (8/15)^2 = 11/225.$$

$$E(XY) = \int_0^1 \int_0^x 8x^2 y^2 \, dy \, dx = 4/9. \quad \text{Cov}(X, Y) = \frac{4}{9} - \frac{4}{5} \cdot \frac{8}{15} = \frac{8}{450}$$

$$\rho = \frac{8/450}{\sqrt{2/75}\sqrt{11/225}} = 0.492$$

$$11.4.4 \quad E(XY) = 2 \left( \frac{1}{2} + \frac{1}{8} \right) + 3 \frac{1}{4} + 8 \frac{1}{8} = 3$$

$$E(X) = 1 \frac{3}{4} + 2 \frac{1}{4} = 5/4$$

$$E(X^2) = 1 \frac{3}{4} + 4 \frac{1}{4} = 7/4$$

$$E(Y) = 1\frac{1}{8} + 2\frac{1}{2} + 3\frac{1}{4} + 4\frac{1}{8} = 19/8$$

$$E(Y^2) = 1\frac{1}{8} + 4\frac{1}{2} + 9\frac{1}{4} + 16\frac{1}{8} = 51/8$$

$$\text{Cov}(XY) = 3 - (5/4)(19/8) = 1/32$$

$$\text{Var}(X) = 7/4 - (5/4)^2 = 3/16$$

$$\text{Var}(Y) = 51/8 - (19/8)^2 = 47/64$$

$$\rho(X, Y) = \frac{1/32}{\sqrt{3/16}\sqrt{47/64}} = \frac{1}{\sqrt{3}\sqrt{47}} = 0.0842$$

**11.4.5**  $\rho(a + bX, c + dY) = \frac{\text{Cov}(a + bX, c + dY)}{\sqrt{\text{Var}(a + bX)\text{Var}(c + dY)}} = \frac{bd\text{Cov}(X, Y)}{\sqrt{b^2\text{Var}(X)d^2\text{Var}(Y)}}$ , the equality in the numerator stemming from Question 3.9.14. Since  $b > 0$ ,  $d > 0$ , this last expression is  $\frac{bd\text{Cov}(X, Y)}{bd\sigma_X\sigma_Y} = \frac{\text{Cov}(X, Y)}{\sigma_X\sigma_Y} = \rho(X, Y)$ .

**11.4.6** To find  $\rho(X, Y)$ , we need the first four moments of  $X$ .

$$E(X) = \sum_{k=1}^n k \left( \frac{1}{n} \right) = \frac{1}{n} \sum_{k=1}^n k = \frac{1}{n} \frac{n(n+1)}{2} = \frac{n+1}{2}$$

$$E(X^2) = \sum_{k=1}^n k^2 \left( \frac{1}{n} \right) = \frac{1}{n} \sum_{k=1}^n k^2 = \frac{1}{n} \frac{n(n+1)(2n+1)}{6} = \frac{(n+1)(2n+1)}{6}$$

$$E(X^3) = \frac{1}{n} \sum_{k=1}^n k^3 = \frac{1}{n} \frac{n^2(n+1)^2}{4} = \frac{n(n+1)^2}{4}$$

$$E(X^4) = \frac{1}{n} \sum_{k=1}^n k^4 = \frac{1}{n} \frac{n(n+1)(2n+1)(3n^2+3n-1)}{30} = \frac{(n+1)(2n+1)(3n^2+3n-1)}{30}$$

Note: We have already encountered the sums of the integers to the first and second powers. The sums for the third and fourth powers can be found in such books of mathematical tables as the CRC Standard Mathematical Tables and Formulae.

$$\begin{aligned} \text{Cov}(X, Y) &= E(XY) - E(X)E(Y) = E(X^3) - E(X)E(X^2) \\ &= \frac{n(n+1)^2}{4} - \frac{(n+1)}{2} \frac{(n+1)(2n+1)}{6} = \frac{(n+1)^2(n-1)}{12} \end{aligned}$$

$$\text{Var}(X) = E(X^2) - E(X)^2 = \frac{(n+1)(2n+1)}{6} - \frac{(n+1)^2}{4} = \frac{(n+1)(n-1)}{12}$$

$$\begin{aligned} \text{Var}(Y) &= E(Y^2) - E(Y)^2 = E(X^4) - E(X^2)^2 = \frac{(n+1)(2n+1)(3n^2+3n-1)}{30} - \frac{(n+1)^2(2n+1)^2}{36} \\ &= \frac{(n+1)(2n+1)(8n^2+3n-11)}{180} = \frac{(n+1)(2n+1)(n-1)(8n+11)}{180} \end{aligned}$$

$$\rho(X, Y) = \frac{\frac{(n+1)^2(n-1)}{12}}{\sqrt{\frac{(n+1)(n-1)}{12} \frac{(n+1)(2n+1)(n-1)(8n+11)}{180}}} = \frac{\sqrt{15}(n+1)}{\sqrt{(2n+1)(8n+11)}}$$

$$\lim_{n \rightarrow \infty} \rho(X, Y) = \lim_{n \rightarrow \infty} \frac{\sqrt{15}(n+1)}{\sqrt{(2n+1)(8n+11)}} = \lim_{n \rightarrow \infty} \frac{\sqrt{15} \left(1 + \frac{1}{n}\right)}{\sqrt{\left(2 + \frac{1}{n}\right) \left(8 + \frac{11}{n}\right)}} = \frac{\sqrt{15}}{4}$$

**11.4.7** (a)  $\text{Cov}(X+Y, X-Y) = E[(X+Y)(X-Y)] - E(X+Y)E(X-Y) = E[X^2 - Y^2] - (\mu_X + \mu_Y)(\mu_X - \mu_Y) = E(X^2) - \mu_X^2 - E(Y^2) + \mu_Y^2 = \text{Var}(X) - \text{Var}(Y)$

(b)  $\rho(X+Y) = \frac{\text{Cov}(X+Y, X-Y)}{\sqrt{\text{Var}(X+Y)\text{Var}(X-Y)}}$ .

By part (a)  $\text{Cov}(X+Y, X-Y) = \text{Var}(X) - \text{Var}(Y)$ .

$\text{Var}(X+Y) = \text{Var}(X) + \text{Var}(Y) + 2\text{Cov}(X, Y) = \text{Var}(X) + \text{Var}(Y) + 0$ .

Similarly,  $\text{Var}(X-Y) = \text{Var}(X) + \text{Var}(Y)$ . Then

$$\rho(X+Y) = \frac{\text{Var}(X) - \text{Var}(Y)}{\sqrt{(\text{Var}(X) + \text{Var}(Y))(\text{Var}(X) + \text{Var}(Y))}} = \frac{\text{Var}(X) - \text{Var}(Y)}{\text{Var}(X) + \text{Var}(Y)}$$

**11.4.8** Multiply the numerator and denominator of Equation 11.4.1 by  $n^2$  to obtain

$$R = \frac{n \sum_{i=1}^n X_i Y_i - \left( \sum_{i=1}^n X_i \right) \left( \sum_{i=1}^n Y_i \right)}{\sqrt{n \sum_{i=1}^n (X_i - \bar{X})^2} \sqrt{n \sum_{i=1}^n (Y_i - \bar{Y})^2}} = \frac{n \sum_{i=1}^n X_i Y_i - \left( \sum_{i=1}^n X_i \right) \left( \sum_{i=1}^n Y_i \right)}{\sqrt{n \sum_{i=1}^n X_i^2 - \left( \sum_{i=1}^n X_i \right)^2} \sqrt{n \sum_{i=1}^n Y_i^2 - \left( \sum_{i=1}^n Y_i \right)^2}}$$

**11.4.9** By Equation 11.4.2  $r = \frac{n \sum_{i=1}^n x_i y_i - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n y_i \right)}{\sqrt{n \sum_{i=1}^n x_i^2 - \left( \sum_{i=1}^n x_i \right)^2} \sqrt{n \sum_{i=1}^n y_i^2 - \left( \sum_{i=1}^n y_i \right)^2}}$

$$= \frac{n \sum_{i=1}^n x_i y_i - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n y_i \right)}{n \sum_{i=1}^n x_i^2 - \left( \sum_{i=1}^n x_i \right)^2} \cdot \frac{n \sum_{i=1}^n x_i^2 - \left( \sum_{i=1}^n x_i \right)^2}{\sqrt{n \sum_{i=1}^n x_i^2 - \left( \sum_{i=1}^n x_i \right)^2} \sqrt{n \sum_{i=1}^n y_i^2 - \left( \sum_{i=1}^n y_i \right)^2}}$$

$$= \hat{\beta}_1 \frac{\sqrt{n \sum_{i=1}^n x_i^2 - \left( \sum_{i=1}^n x_i \right)^2}}{\sqrt{n \sum_{i=1}^n y_i^2 - \left( \sum_{i=1}^n y_i \right)^2}}$$

$$\begin{aligned}
 11.4.10 \quad r &= \frac{n \sum_{i=1}^n x_i y_i - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n y_i \right)}{\sqrt{n \sum_{i=1}^n x_i^2 - \left( \sum_{i=1}^n x_i \right)^2} \sqrt{n \sum_{i=1}^n y_i^2 - \left( \sum_{i=1}^n y_i \right)^2}} \\
 &= \frac{21(7,319,602) - (45,110)(3042.2)}{\sqrt{21(109,957,100) - (45,110)^2} \sqrt{21(529,321.58) - (3042.2)^2}} = 0.730
 \end{aligned}$$

Since  $r^2 = (0.730)^2 = 0.5329$ , we can say that 53.3% of the variability is explained by cigarette consumption.

$$\begin{aligned}
 11.4.11 \quad r &= \frac{n \sum_{i=1}^n x_i y_i - \left( \sum_{i=1}^n x_i \right) \left( \sum_{i=1}^n y_i \right)}{\sqrt{n \sum_{i=1}^n x_i^2 - \left( \sum_{i=1}^n x_i \right)^2} \sqrt{n \sum_{i=1}^n y_i^2 - \left( \sum_{i=1}^n y_i \right)^2}} \\
 &= \frac{12(480,565) - (4936)(1175)}{\sqrt{12(3,071,116) - (4936)^2} \sqrt{12(123,349) - (1175)^2}} = -0.030.
 \end{aligned}$$

The data do not suggest that altitude affects home run hitting.

$$11.4.12 \quad r = \frac{30(7807.36) - (1300.69)(323)}{\sqrt{30(86,754.6939) - (1300.69)^2} \sqrt{30(11,881) - (323)^2}} = -0.388$$

This correlation suggests bonuses may be awarded on some other criteria than performance.

$$11.4.13 \quad r = \frac{17(4,759,470) - (7,973)(8,517)}{\sqrt{17(4,611,291) - (7,973)^2} \sqrt{17(5,421,917) - (8,517)^2}} = 0.762.$$

The amount of variation attributed to the linear regression is  $r^2 = (0.762)^2 = 0.581$ , or 58.1%.

$$11.4.14 \quad r = \frac{36(7051.2633) - (994.77)(254.69)}{\sqrt{36(28,462.1047) - (994.77)^2} \sqrt{36(1816.1417) - (254.69)^2}} = 0.115$$

11.4.15 (a) Putting and earnings

$$r = \frac{96(406.37) - (169.31)(230.87)}{\sqrt{96(298.64) - (169.31)^2} \sqrt{96(734.32) - (230.87)^2}} = -0.311$$

Driving and earnings

$$r = \frac{96(67,658) - (27,989)(230.87)}{\sqrt{96(8,167,723) - (27,989)^2} \sqrt{96(734.32) - (230.87)^2}} = 0.300$$

(b) For putting and earnings,  $r^2 = 0.0970$

For driving and earnings,  $r^2 = 0.09$

## Section 11.5: The Bivariate Normal Distribution

**11.5.1**  $Y$  is a normal random variable with  $E(Y) = 6$  and  $\text{Var}(Y) = 10$ .

$$\text{Then } P(5 < Y < 6.5) = P\left(\frac{5-6}{\sqrt{10}} < Z < \frac{6.5-6}{\sqrt{10}}\right) = P(-0.32 < Z < 0.16) = 0.5636 - 0.3745$$

$= 0.1891$ . By Theorem 11.5.1,  $Y|2$  is normal with  $E(Y|2) =$

$$\mu_Y + \frac{\rho\sigma_Y}{\sigma_X}(2 - \mu_X) = 6 + \frac{\frac{1}{2}\sqrt{10}}{2}(2 - 3) = 5.209$$

$\text{Var}(Y|2) = (1 - \rho^2)\sigma_Y^2 = (1 - 0.25)10 = 7.5$ , so the standard deviation of  $Y$  is  $\sqrt{7.5} = 2.739$ .

$$P(5 < Y|2 < 6.5) = P\left(\frac{5-5.209}{2.739} < Z < \frac{6.5-5.209}{2.739}\right) = P(-0.08 < Z < 0.47) = 0.6808 - 0.4681 = 0.2127$$

**11.5.2** (a) The lemma on page 424 can be used to show that  $X$  and  $Y - \rho X$  are bivariate normal.

Thus it suffices to show that  $\text{Cov}(X, Y - \rho X) = 0$ .

$$\text{Cov}(X, Y - \rho X) = E[X(Y - \rho X)] - E(X)E(Y - \rho X) = E(XY) - \rho E(X^2) - E(X)E(Y) + \rho E(X)^2$$

$$= \text{Cov}(X, Y) - \rho \text{Var}(X) = \text{Cov}(X, Y) - \frac{\text{Cov}(X, Y)}{\sqrt{\text{Var}(X)}\sqrt{\text{Var}(Y)}} \text{Var}(X)$$

$$= \text{Cov}(X, Y) - \text{Cov}(X, Y) = 0, \text{ since } \text{Var}(X) = \text{Var}(Y).$$

(b) The lemma on page 424 can be used to show that  $X + Y$  and  $X - Y$  are bivariate normal.

By Question 11.4.7,  $\text{Cov}(X + Y, X - Y) = \text{Var}(X) - \text{Var}(Y)$ . Since the variances are equal,  $\text{Cov}(X + Y, X - Y) = 0$ , and the two variables are independent.

**11.5.3** (a) 
$$f_{X+Y}(t) = \frac{1}{2\pi\sqrt{1-\rho^2}} \int_{-\infty}^{\infty} \exp\left\{-\frac{1}{2}\left(\frac{1}{1-\rho^2}\right)\left[(t-y)^2 - 2\rho(t-y)y + y^2\right]\right\} dy$$

The expression in the brackets can be expanded and rewritten as

$$t^2 + 2(1+\rho)y^2 - 2t(1+\rho)y = t^2 + 2(1+\rho)[y^2 - ty] =$$

$$t^2 + 2(1+\rho)\left[y^2 - ty + \frac{t^2}{4}\right] - \frac{1}{2}(1+\rho)t^2 = \frac{1-\rho}{2}t^2 + 2(1+\rho)(y - t/2)^2.$$

Placing this expression into the exponent gives

$$f_{X+Y}(t) = \frac{1}{2\pi\sqrt{1-\rho^2}} e^{-\frac{1}{2}\left(\frac{1}{1-\rho^2}\right)\frac{1-\rho}{2}t^2} \int_{-\infty}^{\infty} e^{-\frac{1}{2}\left(\frac{1}{1-\rho^2}\right)2(1+\rho)(y-t/2)^2} dy$$

$$= f_{X+Y}(t) = \frac{1}{2\pi\sqrt{1-\rho^2}} e^{-\frac{1}{2}\left(\frac{t^2}{2(1+\rho)}\right)} \int_{-\infty}^{\infty} e^{-\frac{1}{2}\left(\frac{(y-t/2)^2}{(1+\rho)/2}\right)} dy.$$

The integral is that of a normal pdf with mean  $t/2$  and  $\sigma^2 = (1+\rho)/2$ . Thus, the integral equals  $\sqrt{2\pi(1+\rho)/2} = \sqrt{\pi(1+\rho)}$ . Putting this into the expression for  $f_{X+Y}$  gives

$$f_{X+Y}(t) = \frac{1}{\sqrt{2\pi}\sqrt{2(1+\rho)}} e^{-\frac{1}{2}\left(\frac{t^2}{2(1+\rho)}\right)}, \text{ which is the pdf of a normal variable with } \mu = 0 \text{ and}$$

$$\sigma^2 = 2(1+\rho).$$

(b)  $E(cX + dY) = c\mu_X + d\mu_Y$ ;  $\text{Var}(cX + dY) = c^2\sigma_X^2 + d^2\sigma_Y^2 + 2cd\sigma_X\sigma_Y\rho(X, Y)$

$$11.5.4 \quad E(Y|55) = \mu_Y + \frac{\rho\sigma_Y}{\sigma_X}(55 - \mu_X) = 11 + \frac{0.6\sqrt{2.6}}{\sqrt{1.2}}(55 - 56) = 10.117$$

$\text{Var}(Y|55) = (1 - \rho^2)\sigma_Y^2 = (1 - 0.6^2)2.6 = 1.664$ , so the standard deviation of  $Y$  is  $\sqrt{1.664} = 1.290$ .

$$P(10 \leq Y \leq 10.5|x = 55) = P\left(\frac{10 - 10.117}{1.290} \leq Z \leq \frac{10.5 - 10.117}{1.290}\right) = P(-0.09 \leq Z \leq 0.30) \\ = 0.6179 - 0.4641 = 0.1538$$

The mean of  $\bar{Y}$  also = 10.117. However, the standard deviation is  $1.290 / \sqrt{4} = 0.645$ .

$$\text{Then } P(10.5 \leq \bar{Y} \leq 11|x = 55) = P\left(\frac{10.5 - 10.117}{0.645} \leq Z \leq \frac{11 - 10.117}{0.645}\right) = P(0.59 \leq Z \leq 1.37) \\ = 0.9147 - 0.7224 = 0.1923$$

$$11.5.5 \quad E(X) = E(Y) = 0; \text{Var}(X) = 4; \text{Var}(Y) = 1; \rho(X, Y) = 1/2; k = 1/(2\pi\sqrt{3})$$

$$11.5.6 \quad -(ax^2 - 2uxy + by^2) = -\frac{1}{2}\left(\frac{1}{1-\rho^2}\right)\left(\frac{x^2}{\sigma_X^2} - 2\rho\frac{x}{\sigma_X}\frac{y}{\sigma_Y} + \frac{y^2}{\sigma_Y^2}\right) \text{ so we get the following equations:}$$

$$a = \frac{1}{2}\left(\frac{1}{1-\rho^2}\right)\frac{1}{\sigma_X^2}; b = \frac{1}{2}\left(\frac{1}{1-\rho^2}\right)\frac{1}{\sigma_Y^2}; \text{ and } u = \frac{1}{2}\left(\frac{1}{1-\rho^2}\right)\frac{\rho}{\sigma_X\sigma_Y}.$$

$$\text{From the first two equations we obtain } \frac{1}{\sigma_X^2} = \sqrt{2a(1-\rho^2)} \text{ and } \frac{1}{\sigma_Y^2} = \sqrt{2b(1-\rho^2)}.$$

Substituting these values in the expression for  $u$  gives

$$u = \frac{1}{2}\left(\frac{1}{1-\rho^2}\right)\rho\sqrt{2a(1-\rho^2)}\sqrt{2b(1-\rho^2)} = \rho\sqrt{a}\sqrt{b}, \text{ or } \rho = \frac{u}{\sqrt{a}\sqrt{b}}.$$

From this equation, we get the only conditions on the parameters  $a$ ,  $b$ , and  $u$ :

$$\left|\frac{u}{\sqrt{a}\sqrt{b}}\right| = |\rho| \leq 1 \text{ or } |u| \leq \sqrt{a}\sqrt{b}$$

$$\text{Then we can solve for } \sigma_X^2 \text{ and } \sigma_Y^2 \text{ in terms of } a, b, \text{ and } \rho: \sigma_X^2 = \frac{1}{2}\left(\frac{1}{1-\rho^2}\right)\frac{1}{a};$$

$$\sigma_Y^2 = \frac{1}{2}\left(\frac{1}{1-\rho^2}\right)\frac{1}{b}$$

$$11.5.7 \quad r = -0.453. \quad T_{18} = \frac{\sqrt{n-2}r}{\sqrt{1-r^2}} = \frac{\sqrt{18}(-0.453)}{\sqrt{1-(-0.453)^2}} = -2.16$$

Since  $-t_{0.005,18} = -2.8784 < T_{18} = -2.16 < 2.8784 = t_{0.005,18}$ , accept  $H_0$ .

$$11.5.8 \quad r = \frac{14(710,499) - (2458)(4097)}{\sqrt{14(444,118) - (2458)^2} \sqrt{14(1,262,559) - (4097)^2}} = -0.312$$

$$T_{12} = \frac{\sqrt{n-2}r}{\sqrt{1-r^2}} = \frac{\sqrt{12}(-0.312)}{\sqrt{1-(-0.312)^2}} = -1.14$$

Since  $-t_{.025,12} = -2.1788 < T_{12} = -1.14 < 2.1788 = t_{.025,12}$ , accept  $H_0$ . The data sets appear to be independent.

$$11.5.9 \quad \text{From Question 11.4.11, } r = -0.030. \quad T_{10} = \frac{\sqrt{10}(-0.030)}{\sqrt{1-(-0.030)^2}} = -0.09.$$

Since  $-t_{.025,10} = -2.2281 < T_{10} = -0.09 < 2.2281 = t_{.025,10}$ , accept  $H_0$ .

$$11.5.10 \quad \text{From Question 11.4.13, } r = 0.762. \quad T_{15} = \frac{\sqrt{15}(0.762)}{\sqrt{1-(0.762)^2}} = 4.56.$$

Since  $T_{15} = 4.56 > 2.9467 = t_{.005,15}$  reject  $H_0$ .

$$11.5.11 \quad r = \frac{10(1349.66) - (18.33)(738)}{\sqrt{10(34.1267) - (18.33)^2} \sqrt{10(54756) - (738)^2}} = -0.249$$

Since the correlation coefficient is negative, there is no need to test  $H_1: \rho > 0$ .

To see if there is any effect at all, one could test against  $H_1: \rho \neq 0$ . In that case the test

statistic is  $\frac{\sqrt{8}(-0.249)}{\sqrt{1-(-0.249)^2}} = 0.727$ . Since the test statistic lies between  $-t_{.05,8} = -1.8595$  and

$t_{.05,8} = 1.8595$ , do not reject  $H_0$ .

# Chapter 12: The Analysis of Variance

## Section 12.2: The $F$ Test

**12.2.1** Here  $n = 10$  and  $k = 4$ . To test  $H_0: \mu_A = \mu_B = \mu_C = \mu_D$  at the  $\alpha = 0.05$  level, reject the null hypothesis if  $F \geq F_{.95, 4-1, 10-4} = 4.76$ . At the  $\alpha = 0.10$  level,  $H_0$  is rejected if  $F \geq F_{.90, 3, 6} = 3.29$ . As the ANOVA table shows, the observed  $F$  falls between the two cutoffs, meaning that  $H_0$  is rejected at the  $\alpha = 0.10$  level, but not at the  $\alpha = 0.05$  level.

Source	df	SS	MS	F
Model	3	61.33	20.44	3.94
Error	6	31.17	5.19	
Total	9	92.50		

**12.2.2** Let  $\mu_1$ ,  $\mu_2$ , and  $\mu_3$  denote the true average magnetic field declinations characteristic of the time periods 1669, 1780, and 1865 respectively. To test  $H_0: \mu_1 = \mu_2 = \mu_3$  at the  $\alpha = 0.05$  level, reject the null hypothesis if  $F \geq F_{.95, 3-1, 9-3} = 5.14$ . For these data,  $F = 15.28$ , implying that the magnetic field has shifted over the time period spanned by the eruptions. (Of course, the fact that  $P = 0.004$  is less than  $\alpha = 0.05$  also implies that  $H_0$  should be rejected).

Source	df	SS	MS	F	P
Time	2	90.03	45.01	15.28	0.004
Error	6	17.67	2.95		
Total	8	107.70			

**12.2.3** For these  $n = 30$  observations and  $k = 3$  treatment groups,  $C = T_{..}^2 / n = (422.9)^2 / 30 =$

$$5961.48, \text{ SSTOT} = \sum_{j=1}^3 \sum_{i=1}^{10} y_{ij}^2 - C = 914.1, \text{ and } \text{SSTR} = (121.4)^2 / 10 + (176.1)^2 / 10 +$$

$(125.4)^2 / 10 - 5961.48 = 186.0$ . To test the null hypothesis that the three types of stocks have equal price-earnings ratios, reject  $H_0$  if  $F \geq F_{.99, 3-1, 30-3} = F_{.99, 2, 27}$ . The latter is not a cutoff that appears in Table A.4 of the Appendix. However, its value can be bounded by cutoffs with similar degrees of freedom that are listed:  $F_{.99, 2, 30} = 5.39 < F_{.99, 2, 27} < F_{.99, 2, 24} = 5.61$ . According to the ANOVA table, the observed  $F$  ratio equals 3.45, which implies that  $H_0$  should not be rejected.

Source	df	SS	MS	F
Sector	2	186.0	93.0	3.45
Error	27	728.2	27.0	
Total	29	914.1		

**12.2.4** Let  $\mu_i$  = true average yield for Variety  $i$ ,  $i = 1, 2, \dots, 5$ . Then  $H_0: \mu_1 = \mu_2 = \dots = \mu_5$  should be rejected at the  $\alpha = 0.05$  level if  $F \geq F_{.95, 5-1, 15-5} = 3.48$ . The ANOVA table shows that  $F = 6.39$ , which implies that the differences among the sample means are statistically significant.

Source	df	SS	MS	F	P

**12.2.9** 
$$\begin{aligned} \text{SSTOT} &= \sum_{j=1}^k \sum_{i=1}^{n_j} (Y_{ij} - \bar{Y}_{..})^2 = \sum_{j=1}^k \sum_{i=1}^{n_j} (Y_{ij}^2 - 2Y_{ij}\bar{Y}_{..} + \bar{Y}_{..}^2) = \sum_{j=1}^k \sum_{i=1}^{n_j} Y_{ij}^2 - 2\bar{Y}_{..} \sum_{j=1}^k \sum_{i=1}^{n_j} Y_{ij} + n\bar{Y}_{..}^2 \\ &= \sum_{j=1}^k \sum_{i=1}^{n_j} Y_{ij}^2 - 2n\bar{Y}_{..}^2 + n\bar{Y}_{..}^2 = \sum_{j=1}^k \sum_{i=1}^{n_j} Y_{ij}^2 - n\bar{Y}_{..}^2 = \sum_{j=1}^k \sum_{i=1}^{n_j} Y_{ij}^2 - C, \text{ where } C = T_{..}^2 / n. \end{aligned}$$

Also, 
$$\begin{aligned} \text{SSTR} &= \sum_{j=1}^k \sum_{i=1}^{n_j} (\bar{Y}_{.j} - \bar{Y}_{..})^2 = \sum_{j=1}^k n_j (\bar{Y}_{.j}^2 - 2\bar{Y}_{.j}\bar{Y}_{..} + \bar{Y}_{..}^2) = \sum_{j=1}^k T_{.j}^2 / n_j - 2\bar{Y}_{..} \sum_{j=1}^k n_j \bar{Y}_{.j} + n\bar{Y}_{..}^2 \\ &= \sum_{j=1}^k T_{.j}^2 / n_j - 2n\bar{Y}_{..}^2 + n\bar{Y}_{..}^2 = \sum_{j=1}^k T_{.j}^2 / n_j - C. \end{aligned}$$

**12.2.10** 
$$\begin{aligned} \text{SSTE} / \sigma^2 &= (1 / \sigma^2) \sum_{j=1}^k n_j (\bar{Y}_{.j} - \bar{Y}_{..})^2 = (1 / \sigma^2) \sum_{j=1}^k n_j [(\bar{Y}_{.j} - \mu) - (\bar{Y}_{..} - \mu)]^2 = \\ &= (1 / \sigma^2) \left[ \sum_{j=1}^k n_j [(\bar{Y}_{.j} - \mu)^2 - n(\bar{Y}_{..} - \mu)^2] \right] = \sum_{j=1}^k \left( \frac{\bar{Y}_{.j} - \mu}{\sigma / \sqrt{n_j}} \right)^2 - \left( \frac{\bar{Y}_{..} - \mu}{\sigma / \sqrt{n}} \right)^2. \end{aligned}$$

Since the  $\left(\frac{\bar{Y}_{.j} - \mu}{\sigma / \sqrt{n_j}}\right)$ 's are independent normal random variables, and since  $\left(\frac{\bar{Y}_{..} - \mu}{\sigma / \sqrt{n}}\right)$  can be

written as a linear combination of the  $\left(\frac{\bar{Y}_{.j} - \mu}{\sigma / \sqrt{n_j}}\right)$ , it follows from Fisher's lemma that

$SSTR/\sigma^2$  has a  $\chi^2$  distribution with  $k - 1$  df.

- 12.2.11** Analyzed with a two-sample  $t$  test, the data in Question 9.2.8 require that  $H_0: \mu_X = \mu_Y$  be rejected (in favor of a two-sided  $H_1$ ) at the  $\alpha = 0.05$  level if  $|t| \geq t_{.025, 6+9-2} = 2.1604$ . Evaluating the test statistic gives  $t = (70.83 - 79.33) / 11.31\sqrt{1/6 + 1/9} = -1.43$ , which implies that  $H_0$  should not be rejected. The ANOVA table for the same data shows that  $F = 2.04$ . But  $(-1.43)^2 = 2.04$ . Moreover,  $H_0$  would be rejected with the analysis of variance if  $F \geq F_{.95, 1, 13} = 4.667$ . But  $(2.1604)^2 = 4.667$ .

Source	df	SS	MS	F

Total	17	0.004510			

From Case Study 9.2.1,  $t = 3.88$ ; except for a small rounding error, the square of the observed  $t$  ratio is the same as the observed  $F$  ratio:  $(3.88)^2 = 15.05 \doteq 15.04$ .

**12.2.13**

Source	df	SS	MS	F	P
Law	1	16.333	16.333	1.58	0.2150
Error	46	475.283	10.332		
Total	47	491.617			

The  $F$  critical value is 4.05. For the pooled two-sample  $t$  test, the observed  $t$  ratio is  $-1.257$ , and the critical value is 2.1029. Note that  $(-1.257)^2 = 1.58$  (rounded to two decimal places) which is the observed  $F$  ratio. Also,  $2.1029^2 = 4.05$  (rounded to two decimal places), which is the  $F$  critical value.

## Section 12.3: Multiple Comparisons: Tukey's Method

**12.3.1** For the data in Case Study 12.2.1,  $k = 4$ ,  $r = 6$ ,  $MSE = 79.74$ , and  $D = Q_{.05,4,20}/\sqrt{6} = 3.96/\sqrt{6} = 1.617$ . Let  $\mu_1$ ,  $\mu_2$ ,  $\mu_3$ , and  $\mu_4$  denote the true average heart rates for Non-smokers, Light smokers, Moderate smokers, and Heavy smokers, respectively. Substituting into Theorem 12.3.1 gives the six different Tukey intervals summarized in the table below.

Pairwise Difference	Tukey interval	Conclusion
$\mu_1 - \mu_2$	$(-15.27, 13.60)$	NS
$\mu_1 - \mu_3$	$(-23.77, 5.10)$	NS
$\mu_1 - \mu_4$	$(-33.77, -4.90)$	Reject
$\mu_2 - \mu_3$	$(-22.94, 5.94)$	NS
$\mu_2 - \mu_4$	$(-32.94, -4.06)$	Reject
$\mu_3 - \mu_4$	$(-24.44, 4.44)$	NS

**12.3.2** Let  $\mu_1$ ,  $\mu_2$ , and  $\mu_3$  denote the true average price-earnings ratios for stocks in the financial, industrial, and utility sectors, respectively. The data's ANOVA table shows that  $MSE = 27.0$ . Moreover, in the terminology of Theorem 12.3.1,  $k = 3$ ,  $r = 10$ , and

Source	df	SS	MS	F
Sector	2	186.0	93.0	3.45
Error	27	728.2	27.0	
Total	29	914.1		

$D = Q_{.05,3,27}/\sqrt{10} = 3.51/\sqrt{10} = 1.11$ . The corresponding 95% Tukey confidence intervals are listed in the table.

Pairwise Difference	Tukey interval	Conclusion
$\mu_1 - \mu_2$	$(-11.234, 0.294)$	NS
$\mu_1 - \mu_3$	$(-6.164, 5.364)$	NS
$\mu_2 - \mu_3$	$(-0.694, 10.834)$	NS

**12.3.3** Let  $\mu_C$ ,  $\mu_A$ , and  $\mu_M$  denote the true average numbers of contaminant particles in IV fluids produced by Cutter, Abbott, and McGaw, respectively. According to the analysis of variance,  $H_0: \mu_C = \mu_A = \mu_M$  is rejected at the  $\alpha = 0.05$  level (since the  $P$  value is less than 0.05).

Source	df	SS	MS	F	P
Company	2	113646	56823	5.81	0.014
Error	15	146754	9784		
Total	17	260400			

The three 95% Tukey confidence intervals (based on  $k = 3$ ,  $r = 6$ , and  $D = Q_{.05,3,15}/\sqrt{6} = 3.67/\sqrt{6} = 1.498$ ) show that Abbott and McGaw have the only pairwise difference ( $204.50 - 396.67 = -192.17$ ) that is statistically significant.

Pairwise Difference	Tukey interval	Conclusion
$\mu_C - \mu_A$	$(-78.9, 217.5)$	NS
$\mu_C - \mu_M$	$(-271.0, 25.4)$	NS
$\mu_A - \mu_M$	$(-340.0, -44.0)$	Reject

**12.3.4** Since  $k = 5$  and  $r = 3$ ,  $D = Q_{.05,5,10} / \sqrt{3} = 4.65 / \sqrt{3} = 2.685$ . Also, from the ANOVA table,

Source	df	SS	MS	F
Varieties	4	270.3	67.6	6.39
Error	10	105.7	10.6	
Total	14	375.9		

MSE = 10.6. Substituting into Theorem 12.3.1, then, gives the following set of 95% Tukey confidence intervals:

Pairwise Difference	Tukey interval	Conclusion
$\mu_1 - \mu_2$	$(-14.861, 2.594)$	NS
$\mu_1 - \mu_3$	$(-19.594, -2.139)$	Reject
$\mu_1 - \mu_4$	$(-8.094, 9.361)$	NS
$\mu_1 - \mu_5$	$(-11.727, 5.727)$	NS
$\mu_2 - \mu_3$	$(-13.461, 3.994)$	NS
$\mu_2 - \mu_4$	$(-1.961, 15.494)$	NS
$\mu_2 - \mu_5$	$(-5.594, 11.861)$	NS
$\mu_3 - \mu_4$	$(2.773, 20.227)$	Reject
$\mu_3 - \mu_5$	$(-0.861, 16.594)$	NS
$\mu_4 - \mu_5$	$(-12.361, 5.094)$	NS

**12.3.5** Since  $k = 3$  and  $r = 3$ ,  $D = Q_{.05,3,6} / \sqrt{3} = 4.34 / \sqrt{3} = 2.506$ . MSE = 41.666, so the radius of the intervals is  $D\sqrt{\text{MSE}} = 2.506\sqrt{41.667} = 16.17$ .

Pairwise Difference	Tukey interval	Conclusion
$\mu_1 - \mu_2$	$(-29.5, 2.8)$	NS
$\mu_1 - \mu_3$	$(-56.2, -23.8)$	Reject
$\mu_2 - \mu_3$	$(-42.8, -10.5)$	Reject

**12.3.6** No. Look at the Tukey intervals constructed in Question 12.3.4, for example. The hypotheses  $H_0: \mu_1 = \mu_3$  and  $H_0: \mu_3 = \mu_4$  are rejected, but  $H_0: \mu_1 = \mu_4$  is not.

**12.3.7** Longer. As  $k$  gets larger, the number of possible pairwise comparisons increases. To maintain the same overall probability of committing at least one Type I error, the individual intervals would need to be widened.

## Section 12.4: Testing Subhypotheses with Contrasts

### 12.4.1

Source	df	SS	MS	F
Tube	2	510.7	255.4	11.56
Error	42	927.7	22.1	
Total	44	1438.4		

Subhypothesis	Contrast	SS	F
$H_0: \mu_A = \mu_C$	$C_1 = \mu_A - \mu_C$	264.0	11.95
$H_0: \mu_B = \frac{\mu_A + \mu_C}{2}$	$C_2 = \frac{1}{2}\mu_A - \mu_B + \frac{1}{2}\mu_C$	246.7	11.16

$H_0: \mu_A = \mu_B = \mu_C$  is strongly rejected ( $F_{.99,2,42} \doteq F_{.99,2,40} = 5.18$ ). Theorem 12.4.1 holds true for orthogonal contrasts  $C_1$  and  $C_2$ — $SS_{C_1} + SS_{C_2} = 264.0 + 246.7 = 510.7 = \text{SSTR}$ . Also, both subhypotheses would be rejected—their  $F$  ratios exceed  $F_{.99,1,42}$ .

### 12.4.2

To test  $H_0: (\mu_1 + \mu_2 + \mu_3)/3 = (\mu_4 + \mu_5)/2$ , let  $C = \frac{1}{3}\mu_1 + \frac{1}{3}\mu_2 + \frac{1}{3}\mu_3 - \frac{1}{2}\mu_4 - \frac{1}{2}\mu_5$ .

Then  $\hat{C} = \sum_{j=1}^5 c_j \bar{Y}_j = \frac{1}{3}(48.933) + \frac{1}{3}(55.067) + \frac{1}{3}(59.800) - \frac{1}{2}(48.300) - \frac{1}{2}(51.933) = 4.483$ .

Also,  $SS_C = (4.483)^2 / \left[ \frac{(1/3)^2}{3} + \frac{(1/3)^2}{3} + \dots + \frac{(-1/2)^2}{3} \right] = 72.34$ . From the ANOVA table,

$SSE = 105.7$  and  $n - k = 10$ , so  $H_0$  should be rejected if  $F \geq F_{.95,1,10} = 4.96$ .

Source	df	SS	MS	F
Varieties	4	270.3	67.6	6.39
Error	10	105.7	10.6	
Total	14	375.9		

But,  $F = \frac{72.34/1}{105.7/10} = 6.84$ , implying that the subhypothesis is rejected at the  $\alpha = 0.05$  level.

### 12.4.3

Let  $\mu_1$ ,  $\mu_2$ ,  $\mu_3$ , and  $\mu_4$  denote the true average heart rates for Non-smokers, Light smokers, Moderate smokers, and Heavy smokers, respectively. To test  $H_0: (\mu_2 + \mu_3)/2 = \mu_4$ , let

$C = \frac{1}{2}\mu_2 + \frac{1}{2}\mu_3 - \mu_4$ , so  $\hat{C} = \frac{1}{2}(63.2) + \frac{1}{2}(71.7) - 1(81.7) = -14.25$ .

Also,  $SS_C = (-14.25)^2 / \left[ \frac{(1/2)^2}{6} + \frac{(1/2)^2}{6} + \frac{(-1)^2}{6} \right] = 812.25$ .

From the ANOVA table on p. 642,  $SSE = 1594.833$  and  $n - k = 20$ . Therefore,  $H_0$  should be rejected if  $F \geq F_{.95,1,20} = 4.35$ . Here  $F = \frac{812.25/1}{1594.833/20} = 10.19$ , so  $H_0: (\mu_2 + \mu_3)/2 = \mu_4$  is rejected at the  $\alpha = 0.05$  level.

### 12.4.4

Let  $\mu_1$ ,  $\mu_2$ , and  $\mu_3$  denote the profitability for small medium, and large companies,

respectively. To test  $H_0: \frac{\mu_1 + \mu_2}{2} = \mu_3$  against the alternative that they are not equal, let

$$C = \frac{1}{2}\mu_1 + \frac{1}{2}\mu_2 - \mu_3, \text{ so } \hat{C} = \frac{1}{2}(5.5) + \frac{1}{2}(7.1) - 1(8.8) = -2.5.$$

Also,  $SS_C = (-2.5)^2 / \left[ \frac{(1/2)^2}{7} + \frac{(1/2)^2}{7} + \frac{(-1)^2}{7} \right] = 29.167$ . The given  $SSE = 147.17429$  and

$n - k = 18$ . Therefore,  $H_0$  should be rejected if  $F \geq F_{.90,1,18}$ , which is approximately 3.00.

Here  $F = \frac{29.167/1}{147.17429/18} = 3.57$ , so reject the null hypothesis.

### 12.4.5

	$\mu_A$	$\mu_B$	$\mu_C$	$\mu_D$	$\sum_{j=1}^4 c_j$
$C_1$	1	-1	0	0	0
$C_2$	0	0	1	-1	0
$C_3$	$\frac{11}{12}$	$\frac{11}{12}$	-1	$-\frac{5}{6}$	0

$C_1$  and  $C_3$  are orthogonal because  $\frac{1(11/12)}{6} + \frac{(-1)(11/12)}{6} = 0$ ; also,  $C_2$  and  $C_3$  are orthogonal because  $\frac{1(-1)}{6} + \frac{(-1)(-5/6)}{5} = 0$ .  $\hat{C}_3 = -2.293$  and  $SS_{C_3} = 8.97$ . But  $SS_{C_1} + SS_{C_2} + SS_{C_3} = 4.68 + 1.12 + 8.97 = 14.77 = SSTR$ .

### 12.4.6

To test  $H_0: \mu_A = \mu_B$  and  $H_0: (\mu_A + \mu_B)/2 = (\mu_C + \mu_D)/2$ , the two associated contrasts are  $C_1 = \mu_A - \mu_B$  and  $C_2 = \frac{1}{2}\mu_A + \frac{1}{2}\mu_B - \frac{1}{2}\mu_C - \frac{1}{2}\mu_D$ . Clearly, the two are orthogonal. By inspection, a third orthogonal contrast is  $C_3 = \mu_C - \mu_D$ , which tests the subhypothesis  $H_0: \mu_C = \mu_D$ . Since  $\bar{y}_A = 26.00$ ,  $\bar{y}_B = 40.33$ ,  $\bar{y}_C = 22.00$ , and  $\bar{y}_D = 28.67$ ,  $\hat{C}_1 = -14.33$ ,

$$\hat{C}_2 = 7.83, \text{ and } \hat{C}_3 = -6.67. \text{ Therefore, } SS_{C_1} = (-14.33)^2 / \left[ \frac{(1)^2}{3} + \frac{(-1)^2}{3} \right] = 308.01,$$

$$SS_{C_2} = (7.83)^2 / \left[ \frac{\left(\frac{1}{2}\right)^2}{3} + \frac{\left(\frac{1}{2}\right)^2}{3} + \frac{\left(-\frac{1}{2}\right)^2}{3} + \frac{\left(-\frac{1}{2}\right)^2}{3} \right] = 183.95, \text{ and}$$

$$SS_{C_3} = (-6.67)^2 / \left[ \frac{(1)^2}{3} + \frac{(-1)^2}{3} \right] = 66.73. \text{ According to the ANOVA table, } SSTR = 559 (=$$

$308.01 + 183.95 + 66.73$ ). Each subhypothesis should be rejected if  $F \geq F_{.95,1,8} = 5.32$ .

Source	df	SS	MS	F
Brand	3	559	186	0.66
Error	8	2241	280	
Total	11	2800		

For  $C_1$ ,  $F = \frac{308.01/1}{2241/8} = 1.10$ ; for  $C_2$ ,  $F = \frac{183.95/1}{2241/8} = 0.66$ ; and for  $C_3$ ,  $F = \frac{66.73/1}{2241/8} = 0.24$ .

It follows that none of the three subhypotheses should be rejected.

## Section 12.5: Data Transformations

**12.5.1** Replace each observation by its square root. At the  $\alpha = 0.05$  level,  $H_0: \mu_A = \mu_B$  is rejected. (For  $\alpha = 0.01$ , though, we would fail to reject  $H_0$ ).

Source	df	SS	MS	F	P
Developer	1	1.836	1.836	6.23	0.032
Error	10	2.947	0.295		
Total	11	4.783			

**12.5.2** For each treatment group,  $\bar{y}_{\cdot j} = s_j^2$ . The latter is the relationship that would be expected if the underlying random variable has a Poisson distribution (recall Theorem 4.2.2). Therefore, each observation should be replaced by its square root before doing the analysis of variance (as justified in Example 12.5.1).

**12.5.3** Since  $Y_{ij}$  is a binomial random variable based on  $n = 20$  trials, each data point should be replaced by the arcsin of  $(y_{ij} / 20)^{\frac{1}{2}}$ . Based on those transformed observations,  $H_0: \mu_A = \mu_B = \mu_C$  is strongly rejected ( $P < 0.001$ ).

Source	df	SS	MS	F	P
Launcher	2	0.30592	0.15296	22.34	0.000
Error	9	0.06163	0.00685		
Total	11	0.36755			

## Appendix 12.A.2: The Distribution of $\frac{SSTR/(k-1)}{SSE/(n-k)}$ When $H_1$ Is True

**12.A.2.1** The  $F$  test will have greater power against  $H_1^{**}$  because the latter yields a larger noncentrality parameter than does  $H_1^*$ .

**12.A.2.2** By definition,  $\mu = \frac{1}{n} \sum_{j=1}^k n_j \mu_j$ . If a requirement is imposed to the effect that  $\mu$  must remain constant, then  $H_1$  is inadmissible because the  $H_0$  set of  $\mu_j$ 's imply that  $\mu = 0$ , whereas under  $H_1$ ,  $\sum_{j=1}^k \mu_j = +1$ . However, if no such condition is imposed on  $\mu$ , then  $H_1$  is admissible.

**12.A.2.3**  $M_V(t) = (1-2t)^{-r/2} e^{\gamma t(1-2t)^{-1}}$ , so  $M_V^{(1)}(t) = (1-2t)^{-r/2} \cdot e^{\gamma t(1-2t)^{-1}} [\gamma(-1)(1-2t)^{-2}(-2) + (1-2t)^{-1} \gamma] + e^{\gamma t(1-2t)^{-1}} \left(-\frac{r}{2}\right)(1-2t)^{-(r/2)-1}(-2)$ . Therefore,  $E(V) = M_V^{(1)}(0) = \gamma + r$ .

**12.A.2.4** By Question 12.A.3.3, the expected value of  $V$ , a noncentral  $\chi^2$  random variable with  $r$  degrees of freedom and noncentrality parameter  $\gamma$  is  $E(V) = \gamma + r$ . Therefore,  $\gamma = E(V) - r$ .

**12.A.2.5**  $M_V(t) = \prod_{i=1}^n (1-2t)^{-r_i/2} e^{\gamma_i t/(1-2t)} = (1-2t)^{-\sum_{i=1}^n r_i/2} \cdot e^{\left(\sum_{i=1}^n \gamma_i\right) t/(1-2t)}$ , which implies that  $V$  has a noncentral  $\chi^2$  distribution with  $\sum_{i=1}^n r_i$  df and with noncentrality parameter  $\sum_{i=1}^n \gamma_i$ .

# Chapter 13: Randomized Block Designs

Total	11	9.33			

Since the  $F$  statistic = 8.28 >  $F_{.95,2,6} = 5.14$ , reject  $H_0$ .

**13.2.5** From the Table 13.2.9, we obtain  $MSE = 6.00$ . The radius of the Tukey interval is  $D\sqrt{MSE} = (Q_{.05,3,22} / \sqrt{b})\sqrt{6.00} = (3.56 / \sqrt{12})\sqrt{6.00} = 2.517$ . The Tukey intervals are

Pairwise Difference	$\bar{y}_{.s} - \bar{y}_{.t}$	Tukey Interval	Conclusion
$\mu_1 - \mu_2$	-2.41	(-4.93, 0.11)	NS
$\mu_1 - \mu_3$	-0.54	(-3.06, 1.98)	NS
$\mu_2 - \mu_3$	1.87	(-0.65, 4.39)	NS

From this analysis and that of Case Study 13.2.3, we find that the significant difference occurs not for overall means testing or pairwise comparisons, but for the comparison of “during the full moon” with “not during the full moon”.

### 13.2.6

Source	df	SS	MS	F	P
Quarter	3	14.05	4.68	0.25	0.860
Year	4	43.56	10.89	0.58	0.683
Error	12	255.30	18.78		
Total	19	282.91			

Since the  $F$  statistic for treatments =  $0.25 < F_{.95,3,12} = 3.49$ , accept  $H_0$  that yields are not affected by the quarter. Since the  $F$  statistic for blocks =  $0.58 < F_{.95,4,12} = 3.26$ , accept  $H_0$  that yields are not affected by the year.

**13.2.7** From Question 13.2.2 we obtain the value  $MSE = 0.98$ . The radius of the interval is  $D\sqrt{MSE} = (Q_{.05,3,6} / \sqrt{b})\sqrt{0.98} = (4.34 / \sqrt{4})\sqrt{0.98} = 2.148$ . The Tukey intervals are

Pairwise Difference	$\bar{y}_{.s} - \bar{y}_{.t}$	Tukey Interval	Conclusion
$\mu_1 - \mu_2$	2.925	(0.78, 5.07)	Reject
$\mu_1 - \mu_3$	1.475	(-0.67, 3.62)	NS
$\mu_2 - \mu_3$	-1.450	(-3.60, 0.70)	NS

Error	10	20.57	2.06		
Total	17	233.00			

Since the  $F$  statistic = 4.13 >  $F_{.95,2,10} = 4.10$ , reject  $H_0$ .

- (b) The contrast associated with the subhypothesis is  $C_1 = -\frac{1}{2}\mu_1 - \frac{1}{2}\mu_2 + \mu_3$ , and

$$\hat{C}_1 = -\frac{1}{2}(21.1) - \frac{1}{2}(19.1) + 18.983 = -1.117.$$

$$\text{SS}_{C_1} = \frac{(-1.117)^2}{\left(-\frac{1}{2}\right)^2 / 6 + \left(-\frac{1}{2}\right)^2 / 6 + (1)^2 / 6} = 4.99.$$

$$F = \frac{\text{SS}_{C_1}}{\text{MSE}} = \frac{4.99}{2.06} = 2.42. \text{ Since the observed } F \text{ ratio} = 2.42 < F_{.95,1,10} = 4.96, \text{ accept the}$$

subhypothesis. Let a second orthogonal contrast be  $C_2 = \mu_1 - \mu_2$ .  $\hat{C}_2 = 21.1 - 19.1 = 2.0$ .

$$\text{SS}_{C_2} = \frac{2.0^2}{(1)^2 / 6 + (-1)^2 / 6} = 12.0 \text{ Then } \text{SSTR} = 16.99 = 4.99 + 12.00 = \text{SS}_{C_1} + \text{SS}_{C_2}$$

### 13.2.10

- (a) From Theorem 13.2.2, when  $H_0: \beta_1 = \beta_2 = \dots = \beta_b$  is true,  $\text{SSB}/\sigma^2$  has a chi-square distribution with  $b - 1$  degrees of freedom. Thus,  $E(\text{SSB}/\sigma^2) = b - 1$  or  $E(\text{SSE}) = (b - 1)\sigma^2$ .
- (b) From Theorem 13.2.2,  $\text{SSE}/\sigma^2$  has a chi-square distribution with  $(b - 1)(k - 1)$  degrees of freedom. Thus,  $E(\text{SSE}/\sigma^2) = (b - 1)(k - 1)$  or  $E(\text{SSE}) = (b - 1)(k - 1)\sigma^2$ .

### 13.2.11

$$\begin{aligned} \text{Equation 13.2.2: } \text{SSTR} &= \sum_{i=1}^b \sum_{j=1}^k (\bar{Y}_{.j} - \bar{Y}_{..})^2 = b \sum_{j=1}^k (\bar{Y}_{.j} - \bar{Y}_{..})^2 = b \sum_{j=1}^k (\bar{Y}_{.j}^2 - 2\bar{Y}_{.j}\bar{Y}_{..} + \bar{Y}_{..}^2) \\ &= b \sum_{j=1}^k \bar{Y}_{.j}^2 - 2b\bar{Y}_{..} \sum_{j=1}^k \bar{Y}_{.j} + bk\bar{Y}_{..}^2 = b \sum_{j=1}^k \frac{T_{.j}^2}{b^2} - \frac{2T_{..}^2}{bk} + \frac{T_{..}^2}{bk} = \sum_{j=1}^k \frac{T_{.j}^2}{b} - \frac{T_{..}^2}{bk} = \sum_{j=1}^k \frac{T_{.j}^2}{b} - c \end{aligned}$$

$$\text{Equation 13.2.3: } SSB = \sum_{i=1}^b \sum_{j=1}^k (\bar{Y}_{i.} - \bar{Y}_{..})^2 = k \sum_{i=1}^b (\bar{Y}_{i.} - \bar{Y}_{..})^2 = k \sum_{i=1}^b (\bar{Y}_{i.}^2 - 2\bar{Y}_{i.}\bar{Y}_{..} + \bar{Y}_{..}^2)$$

$$= k \sum_{i=1}^b \bar{Y}_{i.}^2 - 2k\bar{Y}_{..} \sum_{i=1}^b \bar{Y}_{i.} + bk\bar{Y}_{..}^2 = k \sum_{i=1}^b \frac{T_{i.}^2}{k^2} - \frac{2T_{..}^2}{bk} + \frac{T_{..}^2}{bk} = \sum_{i=1}^b \frac{T_{i.}^2}{k} - \frac{T_{..}^2}{bk} = \sum_{i=1}^b \frac{T_{i.}^2}{k} - c$$

$$\text{Equation 13.2.4: } SSTOT = \sum_{i=1}^b \sum_{j=1}^k (Y_{ij} - \bar{Y}_{..})^2 = \sum_{i=1}^b \sum_{j=1}^k (Y_{ij}^2 - 2Y_{ij}\bar{Y}_{..} + \bar{Y}_{..}^2)$$

$$= \sum_{i=1}^b \sum_{j=1}^k Y_{ij}^2 - 2\bar{Y}_{..} \sum_{i=1}^b \sum_{j=1}^k Y_{ij} + bk\bar{Y}_{..}^2 = \sum_{i=1}^b \sum_{j=1}^k Y_{ij}^2 - \frac{2T_{..}^2}{bk} + \frac{T_{..}^2}{bk} = \sum_{i=1}^b \sum_{j=1}^k Y_{ij}^2 - c$$

**13.2.12** Fix  $i = s$ . For  $i \neq s$ ,  $\frac{\partial L}{\partial \beta_i} = 0$ , and  $\frac{\partial L}{\partial \beta_s} = \sum_{j=1}^k 2(y_{sj} - \beta_s - \mu_j)(-1)$ .

Setting  $\frac{\partial L}{\partial \beta_s} = 0$  gives  $\hat{\beta}_s + \frac{1}{k} \sum_{j=1}^k \hat{\mu}_j = \frac{1}{k} \sum_{j=1}^k y_{sj} = \bar{y}_s$ . (13.2.12.1)

Fix  $j = t$ . For  $j \neq t$ ,  $\frac{\partial L}{\partial \mu_j} = 0$ , and  $\frac{\partial L}{\partial \mu_t} = \sum_{i=1}^b 2(y_{it} - \beta_i - \mu_t)(-1)$ . Setting  $\frac{\partial L}{\partial \mu_t} = 0$  gives

$$\frac{1}{b} \sum_{i=1}^b \hat{\beta}_i + \hat{\mu}_t = \frac{1}{b} \sum_{i=1}^b y_{it} = \bar{y}_t$$
 (13.2.12.2)

Rather than use a formal method to solve this system of  $bk$  equations in  $bk$  unknowns, let us make the educated guess that  $\hat{\mu}_j = \bar{y}_{.j}$ . Substituting this into Equation 13.2.12.1 gives

$$\hat{\beta}_s + \frac{1}{k} \sum_{j=1}^k \bar{y}_{.j} = \bar{y}_s, \text{ or } \hat{\beta}_s = \bar{y}_s - \bar{y}_{..} . \text{ Placing } \hat{\beta}_s = \bar{y}_s - \bar{y}_{..} \text{ and } \hat{\mu}_t = \bar{y}_{.t} \text{ into Equation}$$

$$13.2.12.2 \text{ gives } \frac{1}{b} \sum_{i=1}^b (\bar{y}_{s.} - \bar{y}_{..}) + \bar{y}_{.t} = \bar{y}_t . \text{ Since the first term} = 0, \text{ we do have equality.}$$

**13.2.13** (a) False.  $\sum_{i=1}^b \bar{Y}_{i.} = \frac{1}{k} \sum_{i=1}^b \sum_{j=1}^k Y_{ij}$ .  $\sum_{j=1}^k \bar{Y}_{.j} = \frac{1}{b} \sum_{i=1}^b \sum_{j=1}^k Y_{ij}$ . The two expressions are equal only when  $b = k$

(b) False. If neither treatment levels nor blocks are significant, it is possible to have  $F$  variables  $\frac{SSTR / (k-1)}{SSE / (b-1)(k-1)}$  and  $\frac{SSB / (b-1)}{SSE / (b-1)(k-1)}$  both  $< 1$ . In that case both SSTR and SSB are less than SSE.

## Section 13.3: The Paired $t$ Test

**13.3.1** Test  $H_0 : \mu_D = 0$  vs  $H_1 : \mu_D > 0$

$$\bar{d} = \frac{28.17}{19} = 1.483; s_D^2 = \frac{b \sum_{i=1}^b d_i^2 - \left( \sum_{i=1}^b d_i \right)^2}{b(b-1)} = \frac{19(370.8197) - (28.17)^2}{19(18)} = 18.281$$

$$t = \frac{\bar{d}}{s_D / \sqrt{b}} = \frac{1.483}{\sqrt{18.281} / \sqrt{19}} = 1.51. \text{ Since } 1.51 < 1.7341 = t_{.05, 18}, \text{ do not reject } H_0 .$$

**13.3.2** Test  $H_0: \mu_D = 0$  vs.  $H_1: \mu_D < 0$ .

$$s_D^2 = \frac{b \sum_{i=1}^b d_i^2 - \left( \sum_{i=1}^b d_i \right)^2}{b(b-1)} = \frac{13(216) - (-42)^2}{13(12)} = 6.69$$

$$t = \frac{\bar{d}}{s_D / \sqrt{b}} = \frac{-3.23}{\sqrt{6.69} / \sqrt{13}} = -4.50.$$

Since the observed  $t = -4.50 < -1.7823 = -t_{.05,12}$ , we can conclude that the mothered lambs learn more quickly.

**13.3.3** Test  $H_0: \mu_D = 0$  vs.  $H_1: \mu_D \neq 0$ .

$$s_D^2 = \frac{b \sum_{i=1}^b d_i^2 - \left( \sum_{i=1}^b d_i \right)^2}{b(b-1)} = \frac{12(2.97) - (1.3)^2}{12(11)} = 0.257$$

$$t = \frac{\bar{d}}{s_D / \sqrt{b}} = \frac{1.108}{\sqrt{0.257} / \sqrt{12}} = 0.74.$$

$\alpha = 0.05$ : Since  $-t_{.025,11} = -2.2010 < 0.74 < 2.2010 = t_{.025,11}$ , accept  $H_0$ .

$\alpha = 0.01$ : Since  $-t_{.005,11} = -3.1058 < 0.74 < 3.1058 = t_{.005,11}$  accept  $H_0$ .

**13.3.4** Test  $H_0: \mu_D = 0$  vs.  $H_1: \mu_D < 0$ .

$$s_D^2 = \frac{15(363) - (-43)^2}{15(14)} = 17.124$$

$$t = \frac{-2.867}{\sqrt{17.124} / \sqrt{15}} = -2.68$$

Since  $-2.68 < -1.7613 = -t_{.05,14}$ , reject  $H_0$ .

**13.3.5** Test  $H_0: \mu_D = 0$  vs.  $H_1: \mu_D \neq 0$ .

$$s_D^2 = \frac{7(0.1653) - (-0.69)^2}{7(6)} = 0.01621$$

$$t = \frac{-0.09857}{\sqrt{0.01621} / \sqrt{7}} = -2.048.$$

Since  $-t_{.025,6} = -2.4469 < -2.048 < 2.4469 = t_{.025,6}$  accept  $H_0$ .

The square of the observed Student  $t$  statistic  $= (-2.048)^2 = 4.194 =$  the observed  $F$  statistic.

Also,  $(t_{.025,6})^2 = (2.4469)^2 = 5.987 = F_{.95,1,6}$

Conclusion: the two-sided test for paired data is equivalent to the randomized block design test for 2 treatments.

**13.3.6** The quotient  $\frac{\bar{D} - \mu_D}{\sigma_D / \sqrt{b}}$  is standard normal. Also,  $(b-1) S_D^2 / \sigma_D^2$  is chi-square with  $b-1$

degrees of freedom. Then  $\frac{\bar{D} - \mu_D}{\sigma_D / \sqrt{b}} / \sqrt{\frac{(b-1) S_D^2 / \sigma_D^2}{b-1}} = \frac{\bar{D} - \mu_D}{S_D / \sqrt{b}}$  is a Student  $t$  variable with

$b-1$  degrees of freedom. So  $P\left(-t_{\alpha/2, b-1} < \frac{\bar{D} - \mu_D}{S_D / \sqrt{b}} < t_{\alpha/2, b-1}\right) = 1 - \alpha$  or

$$P\left(\bar{D} - t_{\alpha/2, b-1} \frac{S_D}{\sqrt{b}} < \mu_D < \bar{D} + t_{\alpha/2, b-1} \frac{S_D}{\sqrt{b}}\right) = 1 - \alpha.$$

The desired confidence interval is  $\left(\bar{d} - t_{\alpha/2, b-1} \frac{S_D}{\sqrt{b}}, \bar{d} + t_{\alpha/2, b-1} \frac{S_D}{\sqrt{b}}\right)$

For the data of Case Study 13.3.1, the 95% confidence interval is

$$\left(0.47 - 2.2622 \frac{\sqrt{0.662}}{\sqrt{10}}, 0.47 + 2.2622 \frac{\sqrt{0.662}}{\sqrt{10}}\right) = (-0.11, 1.05).$$

**13.3.7** The 95% confidence interval is  $\left(\bar{d} - t_{.025, 11} \frac{S_D}{\sqrt{b}}, \bar{d} + t_{.025, 11} \frac{S_D}{\sqrt{b}}\right)$

$$= \left(0.108 - 2.2010 \frac{\sqrt{0.257}}{\sqrt{12}}, 0.108 + 2.2010 \frac{\sqrt{0.257}}{\sqrt{12}}\right) = (-0.21, 0.43)$$

**13.3.8** From the proof of Theorem 7.4.2 (or refer to Question 13.3.6), if  $T_n$  is a Student  $t$  variable, then  $T_n^2$  is an  $F$  variable with 1 and  $n$  degrees of freedom. Thus, for a Student  $t$  variable with  $n$  degrees of freedom and any  $\alpha$ ,  $P(-u < T_n < u) = P(T_n^2 < u^2) = P(F < u^2)$ , where  $F$  has 1 and  $n$  degrees of freedom. Thus,  $t_{\alpha/2, n}^2 = F_{1-\alpha, 1, n}$ . In the case of randomized block design or the paired two samples,  $n = b - 1$ .

Next we must show that the square of the paired two sample  $t$  statistic equals the randomized block design  $F$  for  $k = 2$ . To do so, SSTR and SSE need to be expressed in terms of  $X$ 's and  $Y$ 's. To that end note that  $\text{SSTR} = \sum_{i=1}^b \sum_{j=1}^2 (\bar{Y}_{.j} - \bar{Y}_{..})^2 = b[(\bar{Y}_{.1} - \bar{Y}_{..})^2 + (\bar{Y}_{.2} - \bar{Y}_{..})^2]$ .

$$\bar{Y}_{..} = \frac{\sum_{i=1}^b X_i + \sum_{i=1}^b Y_i}{2b} = \frac{1}{2} \bar{X} + \frac{1}{2} \bar{Y}, \text{ and } \bar{Y}_{.1} = \bar{X}, \bar{Y}_{.2} = \bar{Y}.$$

$$\begin{aligned} \text{Thus, SSTR} &= b \left[ \left( \bar{X} - \left( \frac{1}{2} \bar{X} + \frac{1}{2} \bar{Y} \right) \right)^2 + \left( \bar{Y} - \left( \frac{1}{2} \bar{X} + \frac{1}{2} \bar{Y} \right) \right)^2 \right] \\ &= b \left[ \left( \frac{1}{2} \bar{X} - \frac{1}{2} \bar{Y} \right)^2 + \left( \frac{1}{2} \bar{Y} - \frac{1}{2} \bar{X} \right)^2 \right] = \frac{b}{2} (\bar{X} - \bar{Y})^2 = \frac{b}{2} \bar{D}^2 \end{aligned}$$

$$\begin{aligned} \text{From Equation 13.2.1, SSE} &= \sum_{i=1}^b \sum_{j=1}^2 (Y_{ij} - \bar{Y}_{.j})^2 - \sum_{i=1}^b \sum_{j=1}^2 (\bar{Y}_{i.} - \bar{Y}_{..})^2 \\ &= \sum_{i=1}^b (Y_{i1} - \bar{Y}_{.1})^2 + \sum_{i=1}^b (Y_{i2} - \bar{Y}_{.2})^2 - 2 \sum_{i=1}^b (\bar{Y}_{i.} - \bar{Y}_{..})^2 = \sum_{i=1}^b (X_i - \bar{X})^2 + \sum_{i=1}^b (Y_i - \bar{Y})^2 - 2 \sum_{i=1}^b (\bar{Y}_{i.} - \bar{Y}_{..})^2. \end{aligned}$$

$$\text{Now } (\bar{Y}_{i.} - \bar{Y}_{..})^2 = \left( \frac{X_i + Y_i}{2} - \frac{\bar{X} + \bar{Y}}{2} \right)^2 = \frac{1}{4} ((X_i - \bar{X}) + (Y_i - \bar{Y}))^2. \text{ So}$$

$$\begin{aligned} \text{SSE} &= \sum_{i=1}^b (X_i - \bar{X})^2 + \sum_{i=1}^b (Y_i - \bar{Y})^2 - \frac{1}{2} \sum_{i=1}^b ((X_i - \bar{X}) + (Y_i - \bar{Y}))^2 \\ &= \frac{1}{2} \sum_{i=1}^b (X_i - \bar{X})^2 + \frac{1}{2} \sum_{i=1}^b (Y_i - \bar{Y})^2 - \sum_{i=1}^b (X_i - \bar{X})(Y_i - \bar{Y}) \end{aligned}$$

$$= \frac{1}{2} \sum_{i=1}^b ((X_i - \bar{X}) - (Y_i - \bar{Y}))^2 = \frac{1}{2} \sum_{i=1}^b (D_i - \bar{D})^2$$

$$\text{The } F \text{ statistic is } \frac{\text{SSTR}}{\text{SSE} / (b-1)} = \frac{\frac{b}{2} \bar{D}^2}{\frac{1}{2} \sum_{i=1}^b (D_i - \bar{D})^2 / (b-1)} = \frac{\bar{D}^2}{\frac{1}{b-1} \sum_{i=1}^b (D_i - \bar{D})^2 / b} = \left( \frac{\bar{D}}{s_D / \sqrt{b}} \right)^2,$$

which is the square of the  $t$  statistic.

**13.3.9** Test  $H_0: \mu_D = 0$  vs.  $H_1: \mu_D < 0$ .

$$s_D^2 = \frac{b \sum_{i=1}^b d_i^2 - \left( \sum_{i=1}^b d_i \right)^2}{b(b-1)} = \frac{7(730.57) - (-28.1)^2}{7(6)} = 102.96, \text{ so } s_D = 10.15$$

$$\bar{d} = \frac{\sum_{i=1}^7 d_i}{7} = \frac{-28.1}{7} = -4.01$$

$$t = t = \frac{\bar{d}}{s_D / \sqrt{b}} = \frac{-4.01}{10.15 / \sqrt{7}} = -1.05$$

Since the observed  $t = -1.05 > -1.9432 = -t_{.05,7}$ , we cannot reject the null hypothesis and conclude better respiratory health for rural inhabitants. However, note that the second data point is an outlier.

# Chapter 14: Nonparametric Statistics

## Section 14.2: The Sign Test

**14.2.1** Here  $x = 8$  of the  $n = 10$  groups were larger than the hypothesized median of 9. The  $P$ -value is  $P(X \geq 8) + P(X \leq 2) = 0.000977 + 0.009766 + 0.043945 + 0.043945 + 0.009766 + 0.000977 = 2(0.054688) = 0.109376$

**14.2.2** The number of data values greater than 0.12 is  $x = 2$ . The test statistic is  $z = 2 - \frac{2-15/2}{\sqrt{15/4}} = -2.84$ . The  $P$ -value is  $P(Z \leq -2.84) = 0.0023$ .  
For the exact binomial test, the  $P$ -value is  $P(X \leq 2)$ , where  $X$  is a binomial random variable with parameters  $n = 15$  and  $p = \frac{1}{2}$ . In this case  $P(X \leq 2) = 0.0037$ .

**14.2.3** The median of  $f_j(y)$  is 0.693. There are  $x = 22$  values that exceed the hypothesized median of 0.693. The test statistic is  $z = \frac{22-50/2}{\sqrt{50/4}} = -0.85$ .  
Since  $-z_{0.025} = -1.96 < -0.85 < z_{0.025} = 1.96$ , do not reject  $H_0$ .

**14.2.4** The critical value for the test is the solution to the equation  $z_\alpha = \frac{y_+^{**} - \frac{1}{2}n}{\sqrt{n/4}}$  or  
 $1.64 = \frac{y_+^{**} - \frac{1}{2}(22)}{\sqrt{22/4}}$ . Then  $y_+^{**} = 14.85$ .  
 $P(Y > 10 | \mu = 11) = P\left(\frac{Y-11}{6} > \frac{10-11}{6} \middle| \mu = 11\right) = P(Z > -0.17) = 1 - 0.4325 = 0.5675$ .  
Thus, when  $\mu = 11$ ,  $Y_+$  is binomial with  $n = 22$  and  $p = 0.5675$ . The power of the test is  
 $P(Y_+ \geq 14.85 | \mu = 11) = P\left(\frac{Y_+ - 22(0.5675)}{\sqrt{22(0.5675)(0.4325)}} > \frac{14.85 - 22(0.5675)}{\sqrt{22(0.5675)(0.4325)}}\right) = P(Z > 1.02)$   
 $= 1 - 0.8461 = 0.1539$ .

**14.2.5**  $P(Y_+ = y_+) = \binom{7}{y_+} \frac{1}{2^7}$ . These values are given in the table.

$y_+$	$P(Y_+ = y_+)$
0	1/128
1	7/128
2	21/128
3	35/128
4	35/128
5	21/128
6	7/128
7	1/128

Possible levels for a one-sided test: 1/128, 8/128, 29/128, etc.

## 14.2.6

$w/1$	$w/1 - 0.618$	sign	$w/1$	$w/1 - 0.618$	sign
0.693	0.075	+	0.654	0.036	+
0.662	0.044	+	0.615	-0.003	-
0.690	0.072	+	0.668	0.050	+
0.606	-0.012	-	0.601	-0.017	-
0.570	-0.048	-	0.576	-0.042	-
0.749	0.131	+	0.670	0.052	+
0.672	0.054	+	0.606	-0.012	-
0.628	0.010	+	0.611	-0.007	-
0.609	-0.009	-	0.553	-0.065	-
0.844	0.226	+	0.933	0.315	+

Note that  $\sum_{k=0}^5 \binom{20}{k} \left(\frac{1}{2}\right)^{20} = \sum_{k=15}^{20} \binom{20}{k} \left(\frac{1}{2}\right)^{20} = 0.021$ . The test is to reject  $H_0$  if  $y_+ \leq 5$  or  $y_+ \geq 15$ .

This gives an  $\alpha$  of 0.042, which is as close as to the desired level of significance of 0.05 as can be achieved with the sign test. From the table, we see that  $y_+ = 11$ . Since  $5 < y_+ = 11 < 15$ , accept  $H_0$ .

## 14.2.7

$y_i$	$y_i - 0.80$	sign	$y_i$	$y_i - 0.80$	sign
0.61	-0.19	-	0.78	-0.02	-
0.70	-0.10	-	0.84	0.04	+
0.63	-0.17	-	0.83	0.03	+
0.76	-0.04	-	0.82	0.02	+
0.67	-0.13	-	0.74	-0.06	-
0.72	-0.08	-	0.85	0.05	+
0.64	-0.16	-	0.73	-0.07	-
0.82	0.02	+	0.85	0.05	+
0.88	0.08	+	0.87	0.07	+
0.82	0.02	+			

$\sum_{k=0}^6 \binom{19}{k} \left(\frac{1}{2}\right)^{19} = 0.0835$ , while  $\sum_{k=0}^7 \binom{19}{k} \left(\frac{1}{2}\right)^{19} = 0.1796$ . Thus, the closest test to one with

$\alpha = 0.10$  is to reject  $H_0$  if  $y_+ \leq 6$ . This test has  $\alpha = 0.0835$ . Since  $y_+ = 9$ , accept  $H_0$ .

Since the observed  $t$  statistic  $= -1.71 < -1.330 = -t_{10,18}$ , the  $t$  test rejects  $H_0$ .

**14.2.8** For this question, we have  $H_0: p = \frac{1}{2}$  vs.  $H_1: p < \frac{1}{2}$ . The table below gives a value of  $u = 3$ ,

the number of times that  $x_i > y_i$ . The test statistic is then  $z = \frac{3 - 15/2}{\sqrt{15/4}} = -2.32$ .

Since  $-2.32 < -1.64 = -z_{.05}$ , we reject  $H_0$ . We can entertain the possibility that hypnosis enhances ESP.

Waking State, $x_i$	Hypnotic State, $y_i$	$x_i > y_i$
18	25	no
19	20	no
16	26	no
21	26	no
16	20	no
20	23	no
20	14	yes
14	18	no
11	18	no
22	20	yes
19	22	no
29	27	yes
16	19	no
27	27	no
15	21	yes

**14.2.9** 
$$z = \frac{y_+ - \frac{1}{2}n}{\sqrt{n/4}} = \frac{19 - \frac{1}{2}(28)}{\sqrt{28/4}} = 1.89. \text{ Accept } H_0, \text{ since } -z_{.025} = -1.96 < 1.89 < 1.96 = z_{.025}.$$

**14.2.10** Assign + if  $Y_i \leq 6$ , and – otherwise. If  $Y_+$  is the number of + signs, then it is binomial with  $n = 36$  and  $p = 0.25$ . The desired test is to reject  $H_0$  if  $Y_+ \leq Y_+^*$  or  $Y_+ \geq Y_+^{**}$  where  $P(Y_+ \leq Y_+^*) = P(Y_+ \geq Y_+^{**}) = \alpha/2$ .

Then  $-1.96 = \frac{Y_+^* - 36(0.25)}{\sqrt{36(0.25)(0.75)}}$ , or  $Y_+^* = 3.91$ . Similarly,  $1.96 = \frac{Y_+^{**} - 36(0.25)}{\sqrt{36(0.25)(0.75)}}$ ,

or  $Y_+^{**} = 14.09$ . If 7 is the true 25th percentile, then  $\theta = 28$ .

$P(Y_i \leq 6) = 6/28 = 0.214$ . In this case  $Y_+$  is binomial with  $n = 36$  and  $p = 0.214$ . Assume the 25th percentile is 7.

The probability of the Type II error is  $P(3.91 < Y_+ < 14.09 | \text{25th percentile is } 7)$

$$= P\left(\frac{3.91 - 36(0.214)}{\sqrt{36(0.214)(0.786)}} < Z < \frac{14.09 - 36(0.214)}{\sqrt{36(0.214)(0.786)}}\right) = P(-1.54 < Z < 2.60) =$$

$$0.9953 - 0.0618 = 0.9335.$$

**14.2.11** From Table 13.3.1, the number of pairs where  $x_i > y_i$  is 7. The  $P$ -value for this test is  $P(U \geq 7) + P(U \leq 3) = 2(0.17186) = 0.343752$ . Since the  $P$  value exceeds  $\alpha = 0.05$ , do not reject the null hypothesis, which is the conclusion of Case Study 13.3.1.

## Section 14.3: Wilcoxon Tests

### 14.3.1

$x_i$	$y_i$	$y_i - x_i$	$ y_i - x_i $	$r_i$	$z_i$	$r_i z_i$
1458	1424	-34	34	1	0	0
1353	1501	148	148	5	1	5
2209	1495	-714	714	8	0	0
1804	1739	-65	65	2	0	0
1912	2031	119	119	4	1	4
1366	934	-432	432	7	0	0
1598	1401	-197	197	6	0	0
1406	1339	-67	67	3	0	0

The sum of the  $r_i z_i$  column is 9. From Table A.6, the critical values of 7 and 29 give  $\alpha = 0.148$ . Since  $7 < w = 9 < 29$ , accept  $H_0$ .

**14.3.2** Section 14.3 gives the expression for  $\prod_{i=1}^4 (1 + e^{it})$ . Then  $\prod_{i=1}^5 (1 + e^{it})$  is  $(1 + e^{5t})$  times

that expression, or  $1 + e^t + e^{2t} + 2e^{3t} + 2e^{4t} + 2e^{5t} + 2e^{6t} + 2e^{7t} + e^{8t} + e^{9t} + e^{10t} + e^{5t} + e^{6t} + e^{7t} + 2e^{8t} + 2e^{9t} + 2e^{10t} + 2e^{11t} + 2e^{12t} + e^{13t} + e^{14t} + e^{15t} = 1 + e^t + e^{2t} + 2e^{3t} + 2e^{4t} + 3e^{5t} + 3e^{6t} + 3e^{7t} + 3e^{8t} + 3e^{9t} + 3e^{10t} + 2e^{11t} + 2e^{12t} + e^{13t} + e^{14t} + e^{15t}$ .

The pdf for each integer  $i$  is the coefficient of  $e^{it}$  divided by  $2^5 = 32$ . The possible  $\alpha$  levels are  $P(W = 15) = 1/32$ ,  $P(W \geq 14) = 1/32 + 1/32 = 1/16$ ,  $P(W \geq 13) = 1/32 + 1/32 + 1/32 = 3/32$ , etc.

### 14.3.3

$x_i$	$y_i$	$y_i - x_i$	$ y_i - x_i $	$r_i$	$z_i$	$r_i z_i$

0.73	-0.07	0.07	11.5	0	0
0.85	0.05	0.05	8.5	1	8.5
0.87	0.07	0.07	11.5	1	11.5

$w$  = sum of the  $r_i z_i$  column = 61. The mean of  $W$  is  $n(n+1)/4 = 95$ . The variance of

$W = n(n+1)(2n+1)/24 = 617.5$ . The observed  $Z$  statistic  $w' = \frac{61-95}{\sqrt{617.5}} = -1.37$ .

Since  $w' = -1.37 < -1.28 = -z_{.10}$ , reject  $H_0$ . The sign test accepted  $H_0$ .

## 14.3.6

$x_i$	$y_i$	$y_i - x_i$	$ y_i - x_i $	$r_i$	$z_i$	$r_i z_i$
14.6	13.8	-0.8	0.8	7	0	0
17.3	15.4	-1.9	1.9	10	0	0
10.9	11.3	0.4	0.4	3.5	1	3.5
12.8	11.6	-1.2	1.2	8.5	0	0
16.6	16.4	-0.2	0.2	1	0	0
12.2	12.6	0.4	0.4	3.5	1	3.5
11.2	11.8	0.6	0.6	6	1	6
15.4	15.0	-0.4	0.4	3.5	0	0
14.8	14.4	-0.4	0.4	3.5	0	0
16.2	15.0	-1.2	1.2	8.5	0	0

$w$  = sum of the  $r_i z_i$  column = 13. From Table A.6, the critical values of 8 and 47 give a test with level of significance 0.048. Since  $8 < w = 13 < 47$ , accept  $H_0$ . The sign test also accepted  $H_0$ .

14.3.7 The signed rank test should have more power since it uses a greater amount of the information in the data.

## 14.3.8

No of trials	$r_i$	$z_i$	$r_i z_i$
2	5	1	5

			$w' = 122.5$

The hypothesis is that lambs with mothers learn faster, that is, test  $H_0: \mu_X = \mu_Y$  vs.  $H_1: \mu_X < \mu_Y$ .

The array below for the rank sum test yields  $w' = 122.5$ . The test statistic is  $z = \frac{122.5 - 175.5}{\sqrt{380.25}} = -2.72$ . Since  $-2.72 < -1.64$ , accept  $H_0$ .

**14.3.9** A reasonable assumption is that alcohol abuse shortens life span. In that case, reject  $H_0$  if the test statistic is less than  $-z_{.05} = -1.64$ . From the table below, we see that  $w' = 72.5$ .

The test statistic is  $z = \frac{72.5 - 99}{\sqrt{198}} = -1.88$ , so reject  $H_0$ .

Age at death	$r_i$	$z_i$	$r_i z_i$
48	2	1	2
66	7	1	7
71	12	1	12

88	19	0	0
90	21	0	0
67	9	0	0
			$w' = 72.5$

**14.3.10** Case Study 9.3.1 asks whether sensory deprivation has any effect on the alpha-wave pattern. Thus, we should use the data in Table 9.3.1 to test  $H_0: \mu_X = \mu_Y$  vs.  $H_1: \mu_X \neq \mu_Y$ . In that case, reject  $H_0$  if the test statistic is less than  $-z_{.025} = -1.96$  or greater than  $z_{.025} = 1.96$ . From the table below, we see that  $w' = 140.5$ . The test statistic is  $z = \frac{140.5 - 105}{\sqrt{175}} = 2.68$ , so reject  $H_0$ .

Frequencies	$r_i$	$z_i$	$r_i z_i$

## Section 14.4: The Kruskal-Wallis Test

### 14.4.1

Group I	Rank	Group II	Rank	Group III	Rank
3	2.5	10	9	20	15
2	1	4	4	9	7
6	6	11	11	18	13
10	9	14	12	19	14
10	9	3	2.5		
5	5				

The sum of the second column in the table is  $r_1 = 32.5$ ; the fourth column,  $r_2 = 38.5$ ; and the sixth column  $r_3 = 49$ . The test statistic is

$$b = \frac{12}{n(n+1)} \left( \frac{r_1^2}{n_1} + \frac{r_2^2}{n_2} + \frac{r_3^2}{n_3} \right) - 3(n+1) = \frac{12}{15(16)} \left( \frac{32.5^2}{6} + \frac{38.5^2}{5} + \frac{49^2}{4} \right) - 3(16) = 5.64.$$

Since  $5.64 < 5.991 = \chi_{95,2}^2$ , accept  $H_0$ .

### 14.4.2

With Dome	Rank	Without Dome	Rank
100.0	12	76.4	2
58.6	1	84.2	7
93.5	10	96.5	11
83.6	4.5	88.8	9
84.1	6	85.3	8
		79.1	3
		83.6	4.5

Summing the second column in the table gives  $r_1 = 33.5$ , and the sum of the fourth column is  $r_2 = 44.5$ .

$$\text{The test statistic is } b = \frac{12}{n(n+1)} \left( \frac{r_1^2}{n_1} + \frac{r_2^2}{n_2} \right) - 3(n+1) = \frac{12}{12(13)} \left( \frac{33.5^2}{5} + \frac{44.5^2}{7} \right) - 3(13) = 0.3.$$

Since  $b = 0.03 < 3.841 = \chi_{95,1}^2$ , accept  $H_0$ .

## 14.4.3

Women	Rank	Men	Rank

Summing the second column in the table gives  $r_{.1} = 110$ , and the sum of the fourth column is  $r_{.2} = 61$ . The test statistic is  $b = \frac{12}{n(n+1)} \left( \frac{r_{.1}^2}{n_1} + \frac{r_{.2}^2}{n_2} \right) - 3(n+1) = \frac{12}{18(19)} \left( \frac{110^2}{8} + \frac{61^2}{10} \right) - 3(19) = 9.13$ . Since  $b = 9.13 > 3.841 = \chi_{.95,1}^2$ , reject  $H_0$ .

## 14.4.5

Non-Smokers	Rank	Light Smokers	Rank	Moderate Smokers	Rank	Heavy Smokers	Rank
69	13	55	2	66	10.5	91	23
52	1	60	7	81	20.5	72	16
71	15	78	18	70	14	81	20.5
58	4.5	58	4.5	77	17	67	12
59	6	62	8	57	3	95	24
65	9	66	10.5	79	19	84	22

$b = \frac{12}{n(n+1)} \left( \frac{r_{.1}^2}{n_1} + \frac{r_{.2}^2}{n_2} + \frac{r_{.3}^2}{n_3} + \frac{r_{.4}^2}{n_4} \right) - 3(n+1) = \frac{12}{24(25)} \left( \frac{48.5^2}{6} + \frac{50^2}{6} + \frac{84^2}{6} + \frac{117.5^2}{6} \right) - 3(25) = 10.715$ . Since  $b = 10.715 > 7.815 = \chi_{.95,3}^2$ , reject  $H_0$ .

## 14.4.6 (a)

Plant 1	Rank	Plant 2	Rank	Plant 3	Rank
905	13.5	1109	26	571	5
1018	20	1155	28	1346	29
905	13.5	835	9	292	3
886	11	1152	27	825	8
958	16	1036	22	676	6
1056	24	926	15	541	4
904	12	1029	21	818	7
856	10	1040	23	90	1
1070	25	959	17	2246	30
1006	19	996	18	104	2

$$b = \frac{12}{n(n+1)} \left( \frac{r_1^2}{n_1} + \frac{r_2^2}{n_2} + \frac{r_3^2}{n_3} \right) - 3(n+1) = \frac{12}{30(31)} \left( \frac{164^2}{10} + \frac{206^2}{10} + \frac{95^2}{10} \right) - 3(31) = 8.11$$

Since  $b = 8.11 > 5.991 = \chi_{.95,2}^2$ , reject  $H_0$ .

(b) The ANOVA table is

Source	df	SS	MS	F
Plant	2	403931.27	201965.63	1.40
Error	27	3891027.4	144112.13	
Total	29	4294958.7		

Since  $F = 1.40 < 3.35 = F_{.95,2,27}$ , accept  $H_0$ .

(c) The change has no effect on the ranks, so  $b$  is the same.

(d)

Source	df	SS	MS	F
Plant	2	678906.87	339453.43	4.24
Error	27	2161202.6	80044.541	
Total	29	2840109.5		

Since  $F = 4.24 > 3.35 = F_{.95,2,27}$ , reject  $H_0$ .

## 14.4.7

Powdered	Rank	Moderate	Rank	Coarse	Rank
146	8.5	150	14.5	141	4
152	16	144	6	138	2
149	12.5	148	10.5	142	5

0.602	1	0.628	2	0.632	3
0.614	1	0.644	3	0.616	2

$$g = \frac{12}{bk(k+1)} \sum_{j=1}^3 r_{.j}^2 - 3b(k+1) = \frac{12}{12(3)(4)} (12.5^2 + 28^2 + 31.5^2) - 3(12)(4) = 17.0$$

Since  $g = 17.0 > 5.991 = \chi_{.95,2}^2$  reject  $H_0$ .

## 14.5.4

High	Rank	Intermediate	Rank	Low	Rank
0.30	3	0.11	1	0.12	2
0.20	1	0.24	2	0.28	3
0.17	2	0.13	1	0.20	3
0.25	2	0.36	3	0.15	1
0.27	2	0.20	1	0.31	3
0.19	3	0.12	1	0.16	2
0.27	3	0.19	1	0.20	2
0.23	3	0.08	1	0.17	2
0.37	3	0.18	1.5	0.18	1.5
0.29	3	0.20	1.5	0.20	1.5

$$g = \frac{12}{bk(k+1)} (r_{.1}^2 + r_{.2}^2 + r_{.3}^2) - 3b(k+1) = \frac{12}{10(3)(4)} (25^2 + 14^2 + 21^2) - 3(10)(4) = 6.2$$

Since  $g = 6.2 > 5.991 = \chi_{.95,2}^2$ , reject  $H_0$ . Analysis of variance of these data would yield an observed  $F = 3.558$ . The critical value is  $F_{0.95,2,18} = 3.555$ . Thus, analysis of variance would also reject the null hypothesis.

## 14.5.5

Contact Desensitization	Rank	Demonstration Participation	Rank	Live Modeling	Rank
8	3	2	2	-2	1
11	3	1	2	0	1
9	2	12	3	6	1
16	3	11	2	2	1
24	3	19	2	11	1

$$g = \frac{12}{5(3)(4)}(14^2 + 11^2 + 5^2) - 3(5)(4) = 8.4$$

Since  $g = 8.4 < 9.210 = \chi_{99,2}$ , accept  $H_0$ . On the other hand, using analysis of variance, the null hypothesis would be rejected at this level.

**14.5.6** The following two equations will be needed in what follows.

$$(1) \bar{r}_{..} = \sum_{j=1}^k r_{.j} = b \frac{k(k+1)}{2} = \frac{bk(k+1)}{2}$$

$$(2) \bar{r}_{..} = \frac{1}{bk} \frac{bk(k+1)}{2} = \frac{k+1}{2}$$

$$\begin{aligned} \sum_{j=1}^k (\bar{r}_{.j} - \bar{r}_{..})^2 &= \sum_{j=1}^k \frac{r_{.j}^2}{b^2} - 2 \sum_{j=1}^k \frac{r_{.j}}{b} \bar{r}_{..} + \sum_{j=1}^k \bar{r}_{..}^2 = \frac{1}{b^2} \sum_{j=1}^k r_{.j}^2 - 2 \frac{k+1}{2} \frac{1}{b} \sum_{j=1}^k r_{.j} + k \frac{(k+1)^2}{4} \\ &= \frac{1}{b^2} \sum_{j=1}^k r_{.j}^2 - (k+1) \frac{1}{b} \frac{bk(k+1)}{2} + k \frac{(k+1)^2}{4} = \frac{1}{b^2} \sum_{j=1}^k r_{.j}^2 - \frac{k(k+1)^2}{4} \end{aligned}$$

$$\begin{aligned} \text{So, } \frac{12b}{k(k+1)} \sum_{j=1}^k (\bar{r}_{.j} - \bar{r}_{..})^2 &= \frac{12b}{k(k+1)} \frac{1}{b^2} \sum_{j=1}^k r_{.j}^2 - \frac{12b}{k(k+1)} \frac{k(k+1)^2}{4} \\ &= \frac{12}{bk(k+1)} \sum_{j=1}^k r_{.j}^2 - 3b(k+1) = g. \end{aligned}$$

## Section 14.6: Testing for Randomness

**14.6.1** (a)

% Change January	$\text{sgn}(y_i - y_{i-1})$	% Change January	$\text{sgn}(y_i - y_{i-1})$
2.0	+	-2.9	+
2.3	-	0.7	-

-0.7	+	2.8	-
1.2	-	0.9	-
-3.4	+	-2.0	-
2.6	-	-2.4	+
1.3	-	3.2	-
0.7	+	2.4	-
0.8	+	-1.9	+
3.1	-	-1.6	
0.2	-		

For these data, the number of runs  $w = 23$ . The test statistic is  $Z = \frac{W - E(W)}{\sqrt{\text{Var}(W)}}$ , where

$E(W) = (2n - 1)/3$  and  $\text{Var}(W) = (16n - 29)/90$ . For these data,  $E(W) = 24.33$  and

$\text{Var}(W) = 6.26$ . Then  $z = \frac{23 - 24.33}{\sqrt{6.26}} = -0.53$ . Since  $-z_{.025} = -1.96 < -0.53 < 1.96 = z_{.025}$ ,

accept  $H_0$  and assume the sequence is random.

(b) The number of runs is  $w = 21$  and  $z = \frac{21 - 24.33}{\sqrt{6.26}} = -1.33$ .

Since  $-z_{.025} = -1.96 < -1.33 < 1.96 = z_{.025}$ , accept  $H_0$  and assume the sequence is random.

**14.6.2** The number of runs is  $w = 17$  and  $z = \frac{17 - 15.67}{\sqrt{3.94}} = 0.67$ .

Since  $-z_{.025} = -1.96 < 0.67 < 1.96 = z_{.025}$ , accept  $H_0$  and assume the sequence is random.

**14.6.3** The number of runs is  $w = 19$ , so  $z = 1.31$ .

Since  $-z_{.025} = -1.96 < 1.31 < 1.96 = z_{.025}$ , accept  $H_0$  and assume the sequence is random.

**14.6.4** The number of runs is  $w = 19$ , so  $z = -0.30$ .

Since  $-z_{.025} = -1.96 < -0.30 < 1.96 = z_{.025}$ , accept  $H_0$  and assume the sequence is random.

**14.6.5** For these data,  $w = 25$ , and  $z = -0.51$ .

Since  $-z_{0.025} = -1.96 < -0.51 < 1.96 = z_{.025}$ , accept  $H_0$  at the 0.05 level of significance and assume the sequence is random.

**14.6.6**
